

*CDA6530: Performance Models of Computers and Networks*

***Project 4 solution: realistic simulation  
using discrete event simulation  
(Fall, 2011)***

# Queuing Network: Machine Repairman Model

- ❑  $c=3$  machines
- ❑ Each fails at rate  $\lambda=0.2/\text{min}$  (expo. distr.)
- ❑ Single repairman, repair rate  $\mu=0.5/\text{min}$
- ❑ Define:  $N(t)$  – no. of machines working
  - ❑  $0 \leq N(t) \leq c$

# Analytical Results

$$\sum_{i=0}^c \pi_i = 1 \Rightarrow \pi_0^{-1} = \sum_{k=0}^c \frac{1}{k!} \left(\frac{\mu}{\lambda}\right)^k$$

$$\pi_k = \frac{1}{k!} \left(\frac{\mu}{\lambda}\right)^k \pi_0$$

□ **Utilization rate?**  $\eta = P(\text{repairman busy}) = 1 - \pi_c$

□ **E[N]?**  $E[N] = \frac{\eta\mu}{\lambda}$

# Pre Simulation

---

---

- ❑ **Physical entities to consider?**
  - ❑  $c=3$  working machines
  - ❑ Do not need to consider repairman since state of machine can represent repairman's state
  - ❑ workingNum: number of working machine
- ❑ **Each entity's data:**
  - ❑ **Status:**
    - ❑ 'working', 'queuing', 'repairing' (w, q, r)
  - ❑ **nextT: next event time**
    - ❑ = expo. with  $\lambda$  (when 'working')
    - ❑ =  $\infty$  (when 'queuing')
      - ❑ How long need to wait depend on others and the queue
    - ❑ = expo. with  $\mu$  (when 'repairing')

# Pre Simulation

No other machines failed

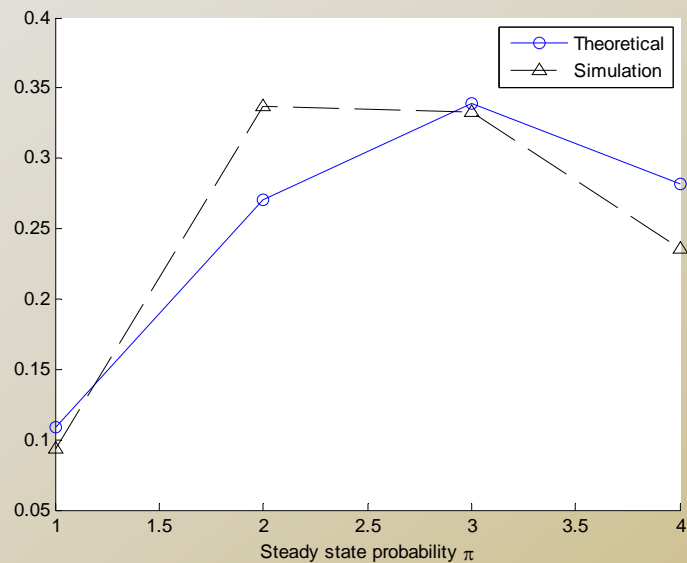

- ❑ Each machine's state transition (above)
- ❑ Need to record the repairman queue
  - ❑ Queue (1:3)
    - ❑ Queue(1)=k: the k-th machine is in repair
    - ❑ Queue(2)=k: the first job in the queue is the k-th machine (k=1,2,..., c)
    - ❑ queueNum: number of machines in the queue

# Pseudo Code

- ❑ **Event List:**
  - ❑ EventList (1:3): next event time of each node
- ❑ **Next event: suppose it is EventList(k)**
  - ❑ Means k-th machine acts, action determined by its current status
  - ❑ currentTime = EventList(k)
  - ❑ If Status(k) == 'w' (broken event)
    - ❑ Update: Queue(), queueNum, workingNum
    - ❑ If k is the first job in queue
      - ❑ Status(k) = 'r', EventList(k) = currentTime + expo( $\mu$ ) (next event: finish repair)
      - ❑ Else: Status(k) = 'q', EventList(k) =  $\infty$
  - ❑ If Status(k) == 'q' (your code is wrong!)
  - ❑ If Status(k) == 'r' (finish repair)
    - ❑ Update: Queue(), **if machine j moves to repair, update EventList(j)**
    - ❑ Update: queueNum, workingNum, repairNum
    - ❑ Status(k) = 'w',
    - ❑ EventList(k) = currentTime + expo( $\lambda$ )

# Post Simulation

- Update Output Data: (i-th event)
  - $\text{Tran}(i) = \text{currentTime}$
  - $\text{SystemState}(i) = \text{workingNum}$

100 repaired

10000 repaired

# *What we learned?*

---

---

- ❑ Three elements in discrete event simulation:
  - ❑ Objects, events, event list
- ❑ **Coding lesson:**
  - ❑ Writing out a code outline is absolutely necessary!
    - ❑ Don't try to write code directly from scratch!
