*CDA6530: Performance Models of Computers and Networks*

***Chapter 8: Statistical Simulation ---  
Discrete-Time Simulation***

# *Simulation Studies*

---

- ❑ **Models with analytical formulas**
  - ❑ Calculate the numerical solutions
    - ❑ Differential equations ---- Matlab Simulink
      - ❑ Or directly solve if has closed formula solutions
    - ❑ Discrete equations --- program code to solve
  - ❑ The mean value formulas for stochastic events
    - ❑ Solutions are only for the mean values
  - ❑ **If you derive models in your paper, you must use real simulation to verify that your analytical formulas are accurate**

# *Simulation Studies*

---

- ❑ **Models without analytical formulas**
  - ❑ Monte Carlo simulation
    - ❑ Generate a large number of random samples
    - ❑ Aggregate all samples to generate final result
    - ❑ Example: use  $U(0,1)$  to compute integral
  - ❑ Discrete-time simulation
    - ❑ Divide time into many small steps
    - ❑ Update system states step-by-step
    - ❑ Approximate, assume system unchanged during a time step
  - ❑ Discrete event simulation (DES)
    - ❑ Accurate
    - ❑ Event-driven

# *Discrete-Time Simulation*

---

- System is assumed to change only at each discrete time tick
  - Smaller time tick, more accurate simulation for a continuous-time physical system
  - At time  $k$ , all nodes' status are only affected by system status at  $k-1$
- **Why use it?**
  - Simpler than DES to code and understand
  - Fast, if system states change very quickly (or many events happening in short time period)

# Discrete-Time Simulation

---

While (simulation not complete){

- 1). Time tick:  $k++$ ;
- 2). For system's node  $i$  ( $i=1,2,\dots$ )
  - 3). Simulate what could happen for node  $i$  during the last time step ( $k-1 \rightarrow k$ ) **based on all nodes status at  $k-1$**
  - 4). Update the state of node  $i$  if something happens to it
- 5). Output time tick  $k$ 's system's states (e.g., status of every node in the system)

}

# *Discrete-Time Simulation*

---

- Note: when computing system node  $i$ 's state at time tick  $k$ , it should be determined only by all other system nodes' states at time tick  $k-1$ 
  - Be careful in step 4): DO NOT use node  $j$ 's newly updated value at current round
    - Newly updated value represents state at the beginning of next round.

# Discrete-Time Simulation

- An example: one line of nodes
  - $X_i(t) = (U - 0.5) + (X_{i-1}(t-1) + X_{i+1}(t-1)) / 2$

```
Simul_N = 1000; n=100; X = ones(n,1);
for k=1:Simul_N,
    U = rand(n,1);
    X(1) = (U(1) - 0.5) + X(2);
    for i=2:n-1,
        X(i) = (U(i) - 0.5) + (X(i-1) + X(i+1)) / 2;
    end
    X(n) = (U(n) - 0.5) + X(n-1);
    % display or save X value for time k
end
```

What's Wrong?

# Discrete-Time Simulation

---

## ❑ Corrected Code:

```
Simul_N = 1000; n=100; X = ones(n,1);
Prior_X = ones(n,1);
for t=1:Simul_N,
    U = rand(n,1);
    Prior_X = X; /* save last time's data */
    X(1) = (U(1) - 0.5) + Prior_X(2);
    for i=2:n-1,
        X(i) = (U(i) - 0.5) + (Prior_X(i-1) + Prior_X(i+1)) / 2;
    end
    X(n) = (U(n) - 0.5) + Prior_X(n-1);
    % display or save X value for time k
end
```

---

---

- ❑ **Another way to do the correct coding:**

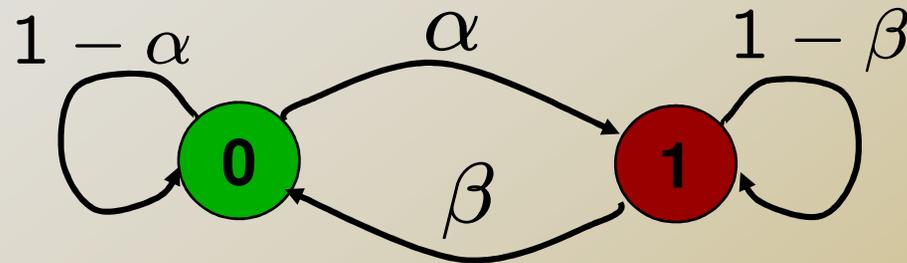

- ❑ `Simul_N = 1000; n=100; X = ones(n,Simul_N);`  
`% X(i, t) is the value of node i at time t.`  
`for t=2:Simul_N,`  
`U = rand(n,1);`  
`X(1, t) = (U(1) - 0.5) + X(2,t-1);`  
`for i=2:n-1,`  
`X(i,t) = (U(i) - 0.5) + (X(i-1, t-1) + X(i+1,t-1)) / 2;`  
`end`  
`X(n,t) = (U(n) - 0.5) + X(n-1, t-1);`  
`% display or save X value for time k`  
`end`

# ***Example: Discrete-Time Markov Chain Simulation***

---

- Simulate N steps
- For each step, use random number U to determine which state to jump to
  - Similar to discrete r.v. generation
- $\pi(i) = m_i/N$ 
  - N: # of simulated steps
  - $m_i$ : number of steps when the system stays in state i.

# Discrete-time Markov Chain Example

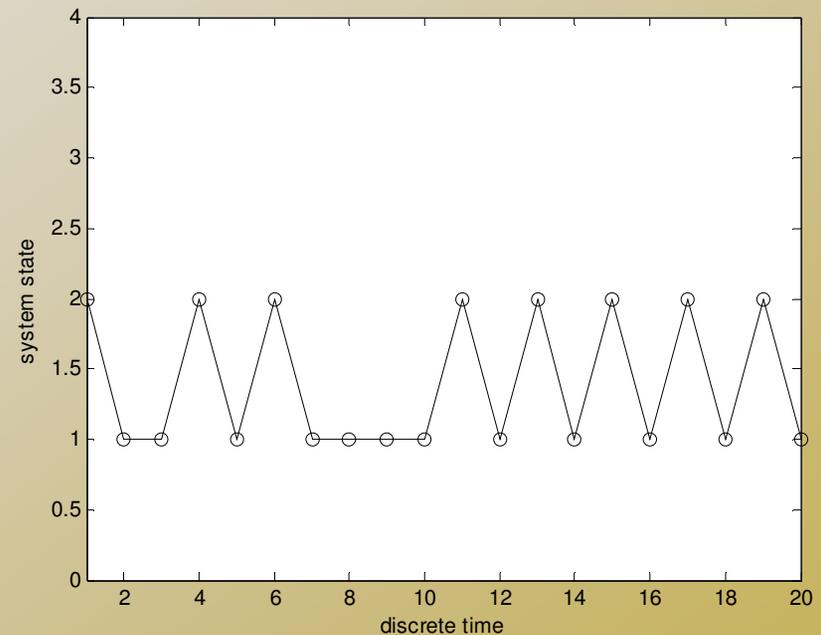

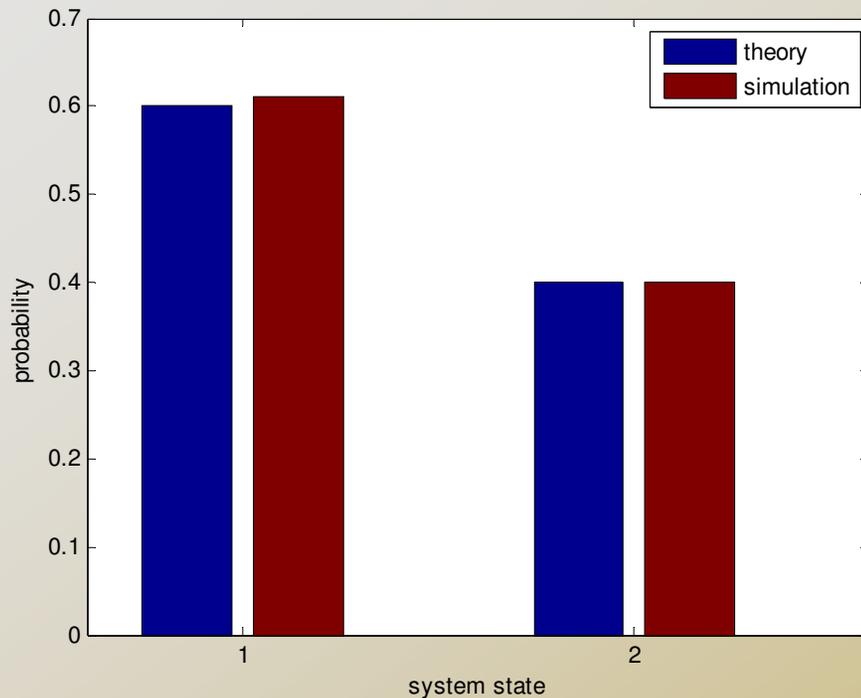

- **Markov on-off model (or 0-1 model)**
- **Q: the steady-state prob.?**

$$\mathbf{P} = \begin{bmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{bmatrix}$$

$$\begin{cases} \pi_0 = (1 - \alpha)\pi_0 + \beta\pi_1 \\ \pi_1 = \alpha\pi_0 + (1 - \beta)\pi_1 \\ \pi_0 + \pi_1 = 1 \end{cases} \Rightarrow \begin{cases} \pi_0 = \frac{\beta}{\alpha + \beta} \\ \pi_1 = \frac{\alpha}{\alpha + \beta} \end{cases}$$

# Simulation result (100 time steps)

- ❑ `bar([Pi_theory Pi_simulation]);`
- ❑ `Pi_theory` and `Pi_simulation` are column vectors

# Appendix: Continuous R.V. simulation

---

- Use inverse transform method:
  - One value of  $U \rightarrow$  one r.v. sample
- Normal distr. use the polar method to generate
- How to draw CDF?
  - Problem: r.v.  $x$  could be any value
  - Solve: determine  $x_i$  points to draw with fixed interval ( $i=1,2,\dots$ )
  - $F(x_i) = P(X \leq x_i) = m/n$ 
    - $n$ : # of samples generated
    - $m$ : # of sample values  $\leq x_i$

# *Continuous R.V.*

---

- **How to draw pdf (probability density function)?**
  - In Matlab, use `histc()` and `bar()`
    - $N = \text{histc}(Y, \text{Edge})$  for vector  $Y$ , counts the number of values in  $Y$  that fall between the elements in the `Edge` vector (which must contain monotonically non-decreasing values).  $N$  is a `length(Edge)` vector containing these counts.
    - Use `bar(Edge,N, 'histc')` to plot the curve
  - The curve plot will have the same curve pattern as  $f(x)$ , but not the same Y-axis values

# ***Pdf example of continuous R.V.***

---

```
% exponential distribution pdf
lambda = 2; sampleN = 1000;
Sample = zeros(1, sampleN);
U = rand(1, sampleN);
for i=1:sampleN,
    Sample(i) = -log(1-U(i))/lambda;
end
Edge = 0:0.1:5;
N = histc(Sample, Edge);
bar(Edge, N, 'histc');
```
