The Document Object Model

• The Document Object Model (DOM) for HTML5 represents a hierarchy tree.

• At the root of every web page or document is the `<html>` element, and the rest of the elements in the page are a branch somewhere along the tree.

• JavaScript uses the DOM for addressing and manipulation a web page beyond what you can do with HTML5 alone.

• The entire DOM tree is a representation of the document that resides in your computer’s memory.
The Document Object Model

• When any part of the DOM tree is addressed, it does so by referencing an element within the tree, beginning with `document`.

• Each element in the tree is addressed in order of the hierarchy beginning with `document`.

• The different elements in a web page are the different properties or methods (built-in functions) of the `document` separated by a dot ( . ).
The Document Object Model

• For example, `document.forms.signup;` would address a form named `signup` within a document.

• A built-in function that does something with the document would appear as:

```javascript
document.write("this is some text.");
```

• The `window` root along with the document has several built-in functions that are useful for manipulating viewing areas of a web page (more later). See the example markup on page 15 in the JavaScript – Part 2 notes to see a use of the `window` root.
Viewing A Document’s DOM Tree

• Current browsers provide developer tools that can display a visual representation of a document’s DOM tree.

• The table on the next page illustrates how to access the developer tools for desktop versions of each of the major browsers.

• For the most part, the developer tools are very similar across the browsers.

• NOTE: For FireFox, you must first install the DOM Inspector add-on available at: https://addons/mozilla/org/en-US/firefox/addon/dom-inspector-6622/.
## Viewing A Document’s DOM Tree

<table>
<thead>
<tr>
<th>Browser</th>
<th>Command to display developer tools</th>
</tr>
</thead>
</table>
| **Chrome** | Windows/Linux: Control + Shift + i  
Mac OS X: Command + Option + i |
| **Firefox** | Windows/Linux: Control + Shift + i  
Mac OS X: Command + Option + i |
| **IE** | F12 |
| **Opera** | Windows/Linux/Mac OS X: From View on tool bar select Developer Tools then select Opera DragonFly (Control + Shift + i should also work) |
| **Safari** | Windows/Linux/Mac OS X: From Edit/Preferences/Advanced check “Show develop menu in menu bar” – then select as needed |
Viewing A Document’s DOM Tree

• We’ll use the markup shown on the next page as an example to view the DOM tree in a couple of the browsers so that you can see what the developer tool looks like.

• The tool in Chrome is shown on page 9, the tool in IE is shown on page 10, the tool in Safari is shown on page 11, and the tool in Opera is shown on page 12.

Viewing A Document’s DOM Tree

• Let’s focus for a bit on the tool as it appears in the Opera browser.

• A node in the DOM tree can be expanded and collapsed using the ▶ and ▼ arrows next to a given node. The screen shot on page 9 illustrates all nodes in the document fully expanded.

• The html node is the root of the tree since it has no parent. Notice in the screen shot on the next page, that if the cursor is placed on the html node, the entire document is highlighted in the top window.
An HTML5 Page

This page contains some basic HTML5 elements. The DOM tree for the document contains a DOM node for every element.

Here's an unordered list:

Here's an unordered list:

- One
- Two
- Three
Viewing A Document’s DOM Tree

• In addition to viewing a document’s DOM structure, the developer tools in each browser typically allow you to view and modify styles, view and debug JavaScripts used in the document, view the resources (such as images) used by the document, and so on.

• I would suggest that you become familiar with the developer tool in whichever browser you intend to use as your primary development environment.
The Document Object Model

• To get a better sense of how the DOM works with your web page and JavaScript, it helps to see what can be done with a web page’s windows – the viewing part of your web page.

• The following example shows how to load a new window from the current document, leaving the current page in place.
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>Open Another Page</title>
    <meta charset="utf-8">
    <style type="text/css">
        a {
            text-decoration: none;
            color: #cc0000;
            font-size: 24px;
        }
        header {
            text-align: center;
        }
    </style>
  </head>
  <body>
    <header>
      <a href="#" onClick="someOtherWindow()">Click to Open New Window</a>
    </header>
    <script type="text/javascript">
        function someOtherWindow()
        {
            window.open("OtherWindow.html","ow","width=400,height=200");
        }
    </script>
  </body>
</html>
<!DOCTYPE html>
<html lang="en">
<head>
    <title>The Other Window</title>
    <meta charset="utf-8">
    <style type="text/css">
        h1, h4 {
            font-family: Verdana, Geneva, sans-serif; color: #930;
        }
        a {
            text-decoration: none; color: #cc0000; text-align: center;
        }
    </style>
</head>
<body>
    <h1>This window has an important message...</h1>
    <h4>Stand by while I figure out what it is....</h4>
    <a href="#" onClick="shutItDown()">Shut the window!</a>
    <script type="text/javascript">
        function shutItDown()
        {
            window.close();
        }
    </script>
</body>
</html>
Click to Open New Window

This window has an important message...

Stand by while I figure out what it is....

Shut the window!
The Document Object Model

- Up to this point when we’ve written markup where one page is linked to another page, the current page has disappeared as soon as the user clicks the link to the other page.

- Now, using this little bit of JavaScript you can “talk” directly to the page and tell it you want a new window of a specified size to open while the current window stays open.
HTML5 Elements And The DOM

• In order to give you an even better idea of how to work with the DOM in HTML5, certain new elements require DOM references within the tags themselves.

• One such new element is the `<output>` element. Currently, Opera is the only browser that has fully implemented this element, so again, you should test the following markup using Opera.

• When you use the `<output>` element, you can place the results of a calculation directly on the webpage. You don’t have to build a JavaScript function or even a simple script.
However, the materials within an output element must follow the same DOM rules as with JavaScript.

The output container doesn’t require content between the opening and closing tags. However, all of the calculations must be within the `<output>` element itself.

The `<output>` element works in conjunction with the `<form>` element and we’ve already covered that and your current project deals with that as well.

Now we want to focus on the DOM structure in the `<output>` element’s use. Consider the following markup.
<!DOCTYPE html>
<html lang="en">
<head>
    <meta charset="utf-8">
    <title>A Simple Shopping Cart Cost Calculator</title>
    <style type="text/css">
        body { font-family: Verdana, Geneva, sans-serif; background-color:#F6E85F; color:#042845; }
        input { background-color:#F6E85F; }
        h1 { color:#E8A5B5; background-color:#042845; text-align:center; }
        h3 { color:#FFC545; background-color:#FFA033; }
    </style>
</head>
<body>
    <header>
        <h1>Shopping Calculator</h1>
    </header>
    <form>
        <input name="cost" type="number" &nbsp;Cost &nbsp;<br />
        <input name="tax" type="number" &nbsp;Tax--Enter as decimal percent (e.g., .06) &nbsp;<br />
        <h3> &nbsp;Total = $ &nbsp;<br />
        <output onforminput="value = cost.valueAsNumber * tax.valueAsNumber + cost.valueAsNumber"></output>
        </h3>
    </form>
</body>
</html>
This output is produced via the `onforminput` event handler.
Analysis Of The Previous Example

• Within the form container, two input elements are named *cost* and *tax*. In the context of the DOM, each is an object with certain properties, one of which is *valueAsNumber*. This is illustrated by the screen shot on the next page.

• Whatever number character is in the input form is treated as an actual number instead of a text character. The *valueAsNumber* is a property of the `<input>` element and not the *number* type that was used in the element. (I could have used a *text* value for the input type and had the same results using the input element.) Recall that the *number* type simply provides the selection list (see Inside HTML5 – Part 4 – Forms, pages 56-58 for more details.)
Shopping Cart Cost Calculator

Cost

Tax -- Enter as decimal percent (e.g., .06)

```html
<form>
  <input name="cost" type="number" />
  Cost
  <br />
  <input name="tax" type="number" />
  Tax -- Enter as decimal percent (e.g., .06)
  <br />
  <h3>Total = $</h3>
  <output id="value" onforminput="value = cost.valueAsNumber * tax.valueAsNumber + cost.valueAsNumber" />
</form>
```

valueAsNumber NaN

```
+ HTMLInputElementPrototype
+ HTMLInputElement
+ HTMLElementPrototype
+ Element
```

© Dr. Mark Llewellyn
Analysis Of The Previous Example

• The number type simply provides the “spinner” input control (the up/down arrows) window, but values in the input window are not automatically converted into numeric data.

• Notice how the `onforminput` event handler works. As information is entered into the form, the results are calculated and displayed.

• After the user has entered the cost, but before they have entered the tax, the result will be displayed as NaN (Not a Number) because the tax value is null, resulting in a non-numeric result. However, as soon as the tax is entered, the output changes to a number. See the next two screen shots.
The user has only entered the cost amount. At this point the tax value is null so the total is not a numeric value and \texttt{NaN} is written as the total.
The user has now entered both numbers into the form and the total is correctly calculated and displayed.

MacIntel
Traversing And Modifying A DOM Tree

• The DOM enables you to programmatically access a document’s elements, allowing you to modify its contents dynamically using JavaScript.

• The HTML5/CSS/JavaScript example we’ll use is available on the course website, I did not include the markup in these notes. The example will allow you to traverse the DOM tree, modify nodes and create or delete content dynamically.

• The CSS class highlighted is applied dynamically to elements in the document as they are selected, added, or deleted using the form at the bottom of the document.

• As you play around with this example, be sure to do it in the developer tool so that you can see the DOM tree as well.
Traversing And Modifying A DOM Tree

• The HTML5 document is manipulated dynamically by modifying its DOM tree.

• Each element has an id attribute, which is also displayed in square brackets at the beginning of the element (so you can see which element is which).

• The click event listeners are registered in the JavaScript (available on the course website) for the six buttons that call corresponding functions to perform the actions described by the button’s values.
The JavaScript begins by declaring two variables.

Variable `currentNode` keeps track of the currently highlighted node (the initially highlighted node is the `[bigheading]`, the functionality of each button depends on which node in the document (DOM tree) is currently selected.

The function `start` registers the event handlers for the buttons, then initializes the `currentNode` to the `<h1>` element, the element with `id = bigheading`.

Note that the function `start` is called when the window’s `load` event occurs.
Traversing And Modifying A DOM Tree

• The JavaScript variable idcount is used to assign a unique id to any new elements that are dynamically created by the user.

• The remainder of the JavaScript contains the event handling functions for the buttons and two helper functions (switchTo and createNewNode) that are called by the event handlers.

• Over the next few pages, I’ll explain how each of the buttons and its corresponding event handler works. Before reading on, you should download the markup, the style sheet, and the JavaScript files and play around with the page a bit to get a feel for what’s happening with the page as the user manipulates the page.
Finding and Highlighting an Element Using 
getElementById, setAttribute and getAttribute

• The first row of the form allows the user to enter the id of an element into the text field and click the Get By id button to find and highlight the element.

• The button’s click event calls function byId().

```javascript
// get and highlight an element by its id attribute
function byId() {
    var id = document.getElementById("gbi").value;
    var target = document.getElementById(id);

    if (target) {
        switchTo(target);
    }
} // end function byId
```
• First, the `byId()` function uses `getElementById` to assign the contents of the text field to the variable `id`.

• Next, the `byID()` function uses `getElementById` to find the element whose id attribute matches the value of variable `id` and assigns this to the variable `target`.

• If an element is found with the specified `id`, and object is returned; otherwise, `null` is returned.

• Next, the function checks to see whether `target` is an object (any object used as a boolean expression is true, while `null` is false). If `target` evaluates to true, the `switchTo()` helper function is called with `target` as its argument.
Finding and Highlighting an Element Using 
getElementById, setAttribute and getAttribute

- The `switchTo()` helper function is used a lot in this JavaScript to highlight an element in the page. The current element is given a yellow background (via the CSS class `highlighted`).

- The DOM element methods `setAttribute` and `getAttribute` allow you to modify and get an attribute’s value, respectively.

- The function `switchTo` function uses the `setAttribute` method to set the current node’s class attribute to the empty string. This clears the class attribute to remove the highlighted class from the `currentNode` before the new node is highlighted.
The last thing the byID function does is uses the getAttribute method to get the currentNode’s id and assign it to the input field’s value property.

This isn’t necessary when this helper function is called by byID, but as you’ll see later, other functions call switchTo as well. In these cases, this line ensures that the text field’s value contains the currently selected node’s id.

Notice that setAttribute was not used to change the value of the input field. Methods setAttribute and getAttribute do not work for user-modifiable content, such as the value displayed in an input field.
[bigheading] HTML5 DOM Tree Demo Page

[smallheading] Element Functionality

[para1] The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

[para2] For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3.

[para3] The buttons below demonstrate:

- [item1] `getElementById` and `parentNode`
- [item2] `insertBefore` and `appendChild`
- [item3] `replaceChild` and `removeChild`
[smallheading] Element Functionality

[para1] The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

[para2] For more information, check out the "JavaScript lecture notes on the course website [link]".
User enters “para3” in the text field for the “Get By Id” button. When they click the button the value the user entered into the text field is extracted and the `byId()` function is triggered.
User enters “para3” in the text field for the “Get By Id” button. When they click the button the value the user entered into the text field is extracted and the `byId()` function is triggered.
• The second and third rows of the form allow the user to create a new element and insert it before or as a child of the current node, respectively.

• If the user enters text in the second text field and clicks the Insert Before button, the text is placed in a new paragraph element, which is inserted into the document before the currently selected element.

• The Insert Before button’s click event calls function insert().
Creating and Inserting New Elements Using `insertBefore` and `appendChild`

- The `insert()` function calls the `createNewNode()` function, passing it the value of the “ins” input field as an argument.

- The helper function `createNewNode()` creates a paragraph node that contains the text passed to it.

```javascript
// insert a paragraph element before the current element
// using the insertBefore method
function insert()
{
    var newNode = createNewNode(
        document.getElementById( "ins" ).value );
    currentNode.parentNode.insertBefore( newNode, currentNode );
    switchTo( newNode );
} // end function insert
```
Creating and Inserting New Elements Using `insertBefore` and `appendChild`

- Function `createNewNode()` creates a `<p>` element using the document’s `createElement` method, which creates a new DOM node, taking the tag name as an argument.

- The `createElement` method creates an element...it does **not** insert the element on the page.

```javascript
// helper function that returns a new paragraph node containing
// a unique id and the given text
function createNewNode( text )
{
    var newNode = document.createElement( "p" );
    nodeId = "new" + idcount;
    ++idcount;
    newNode.setAttribute( "id", nodeId ); // set newNode's id
text = "[" + nodeId + "]" + text;
    newNode.appendChild( document.createTextNode( text ) );
    return newNode;
} // end function createNewNode
```
Creating and Inserting New Elements Using `insertBefore` and `appendChild`

- To create the new element, a unique `id` for it is created by concatenating the string “new” with the current value of `idcount`.

- The `setAttribute` function is then called to set the `id` of the new element.

- The value of the text is concatenated with the square brackets used to identify the nodes to the user.

- Then the document’s `createTextNode` method is called to create a node that contains only text. This new node is then used as the argument to the `appendChild` method, which inserts a child node after any existing children of the node on which it is called.
Creating and Inserting New Elements Using `insertBefore` and `appendChild`

- After the `<p>` element is created by `createNewNode` that function returns the new node to the `insert` function, where it’s assigned to the variable `newNode`.

- The `newNode` is then inserted before the currently selected node.

- The `parentNode` property contains a node’s parent. This property is used in the `insert` function to get the current node’s parent. Then the `insertBefore` method is invoked on the parent node with `newNode` and `currentNode` as its arguments. This causes `newNode` to be inserted as a child of the parent directly before `currentNode`. 
Creating and Inserting New Elements Using `insertBefore` and `appendChild`

- Finally, the `switchTo` helper function is called to set the highlighted class on the newly created element.
- The input field and button on the third line of the input form allows the user to append a new paragraph node as a child of the current element.
- This is done in a similar manner to the `Insert Before` button’s `insert` function. However, in this case the function `appendNode` creates the new node and inserts it as a child of the current node. Examine the JavaScript more closely to see how this mirrors the insert function and also how it differs.
User selects [para3] then enters new text and clicks Insert Before button. HTML effect shown on next page.
HTML5 DOM Tree Demo Page

Element Functionality

The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

For more information, check out the "JavaScript lecture notes on the course web site [link]."

This is a new dynamically inserted <p> element

The buttons below demonstrate:

- getElementsById and parentNode
- insertBefore and appendChild
- replaceChild and removeChild

<table>
<thead>
<tr>
<th>Get By id</th>
</tr>

[bigheading] HTML5 DOM Tree Demo Page

[smallheading] Element Functionality

[para1] The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

[para2] For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3.

[new0] This is a new dynamically inserted <p> element

[para3] The buttons below demonstrate:(list)

• [item1] getElementsByTagName and parentElement
Replacing and Removing Elements Using `replaceChild` and `removeChild`

- The next two buttons on the input form provide the user with the ability to replace the current element with a new `<p>` element or simply to remove the element entirely.

- When the user clicks the Replace Current button, the function `replaceCurrent` is called.

- In function `replaceCurrent`, the `createNewNode` helper function is called in much the same manner as it was when the `InsertBefore` or `AppendChild` buttons were clicked.

- The user’s text is retrieved from the input field in the form and the parent of the current node is determined, then the `replaceChild` method is invoked on the parent.
Replacing and Removing Elements Using `replaceChild` and `removeChild`

- The `replaceChild` method takes two arguments, the first of which is the new node to be inserted, and the second is the node to be replaced.

```javascript
// replace the currently selected node with a paragraph node
function replaceCurrent() {
    var newNode = createNewNode(
        document.getElementById("replace").value);
    currentNode.parentNode.replaceChild( newNode, currentNode);
    switchTo( newNode);
} // end function replaceCurrent
```
[bigheading] HTML5 DOM Tree Demo Page

[smallheading] Element Functionality

[para1] The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

[para2] For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3.

[para3] The buttons below demonstrate:

- [item1] `getElementById` and `parentNode`
- [item2] `insertBefore` and `appendChild`
- [item3] `replaceChild` and `removeChild`

User selects [para1] then enters new text and clicks Replace Current button. HTML effect shown on next page.

[smallheading] Element Functionality

[new0] This paragraph has been dynamically altered by JavaScript!!!

[para2] For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3.

[para3] The buttons below demonstrate:

- [item1] `getElementById` and `parentNode`
- [item2] `insertBefore` and `appendChild`
- [item3] `replaceChild` and `removeChild`

```
new0
Get By Id
Insert Before
Append Child
Replace Current
Remove Current
Get Parent
```
HTML5 DOM Tree Demo Page

Element Functionality

This paragraph has been dynamically altered by JavaScript!!!
• Clicking the Remove Current button calls the remove function in the JavaScript which removes the currently selected element entirely and highlights the parent.

• If the node’s parent is the body element, an error message is displayed to indicate that a top level element cannot be deleted.

• The next page illustrates this error condition.
User selects [para1] then clicks Remove Current button. JavaScript pops up the alert that a top-level element cannot be deleted.
Replacing and Removing Elements Using `replaceChild` and `removeChild`

- In general, `parent.removeChild(child)` looks in a parent’s list of children for child and removes it.

```javascript
// remove the current node
function remove()
{
    if ( currentNode.parentNode == document.body )
        alert( "Can't remove a top-level element." );
    else
    {
        var oldNode = currentNode;
        switchTo( oldNode.parentNode );
        currentNode.removeChild( oldNode );
    }
} // end function remove
```
User selects item2] then clicks Remove Current button. HTML effect shown on next page.
[bigheading] HTML5 DOM Tree Demo Page

[smallheading] Element Functionality

[para1] The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

[para2] For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3."

[para3] The buttons below demonstrate:
(list)

- [item1] `getElementById` and `parentNode`
- [item3] `replaceChild` and `removeChild`
The final piece of functionality in this DOM demo is the button that allows the user to identify the parent of the selected element.

This is done by calling the `parent` function. This function simply gets the parent node, again making sure it's not the body element since we will not allow selecting the entire body element.

When the parent node is determined, the `switchTo` function is called to highlight the parent node.

This sequence is illustrated by the next two slides.
The Document Object Model (DOM) allows for quick, dynamic access to all elements in an HTML5 document for manipulation with JavaScript.

For more information, check out the "JavaScript lecture notes on the course web site [link] JavaScript - Part 1, 2, and 3."

The buttons below demonstrate:

- `getElementById` and `parentNode`
- `insertBefore` and `appendChild`
- `replaceChild` and `removeChild`

User selects `item2` then clicks `Get By id`. The `item2` element is highlighted. Then the user clicks the `Get Parent` button. HTML effect shown on next page.
The parent of [item2] is now highlighted and identified in the get By Id text field.
