University of Central Florida
Introduction to JDBC

• JDBC was originally an acronym for Java Data Base Connectivity. Sun marketing now states this is no longer an acronym but the official name.

• JDBC is made up of about two dozen Java classes in the package java.sql. These classes provide access to relational data stored in a database or other table-oriented forms (like Excel, etc.).

• JDBC allows the programmer to use modern database features such as simultaneous connections to several databases, transaction management, precompiled statements with bind variables, calls to stored procedures, and access to metadata in the database dictionary.

• JDBC supports both static and dynamic SQL statements.

• The evolution of JDBC is shown on the next slide.
# Evolution of JDBC

<table>
<thead>
<tr>
<th>JDBC Version</th>
<th>Bundled with</th>
<th>Package Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC 1.0 (previously called 1.2)</td>
<td>JDK 1.1</td>
<td>java.sql</td>
<td>Basic Java client to database connectivity.</td>
</tr>
<tr>
<td>JDBC 2.0 core API</td>
<td>JDK 1.2 and later</td>
<td>java.sql</td>
<td>Added features such as scrollable result sets, batch updates, new data types for SQL-3, and programmable updates using the result set.</td>
</tr>
<tr>
<td>JDBC 2.1 optional API</td>
<td>Not bundled</td>
<td>javax.sql</td>
<td>Incremental improvement and additions over the 2.0 API.</td>
</tr>
<tr>
<td>JDBC 3.0 core API</td>
<td>JDK 1.4 and later</td>
<td>java.sql</td>
<td>Adds support for connection pooling, statement pooling, and a migration path to the Connector Architecture.</td>
</tr>
</tbody>
</table>
Connecting To A Database

• A database works in the classic client/server fashion. There is one database and many clients talk to it. (Larger applications may have multiple databases, but they can be considered independently for our purposes.)

• As we’ve seen in the earlier sections of notes dealing with networking, the clients are typically remote systems communicating over TCP/IP networks.

• In a 2-tier system, the clients talk directly to the database while in a 3-tier system, the clients talk to a business logic server which in turn talks to the database. The business logic server would also contain server-side JDBC functionality.
Connecting To A Database (cont.)

- A JDBC driver is typically available from the database vendor of the database to which you wish to connect.

- There are several different kinds of drivers depending on whether it was written in Java or native code, or whether it talks directly to the database or through another database access protocol (such as Microsoft’s ODBC). From an application programmer’s point of view, none of this matters very much as long as you have a working JDBC driver, you really don’t care how it works (although your client may if it’s too slow!).

- JDBC supports four categories of drivers which are detailed in the table on the next page.
# JDBC Driver Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><strong>JDBC-to-ODBC Bridge Driver</strong> – connects Java to a Microsoft ODBC (Open Database Connectivity) data source. This driver requires the ODBC driver to be installed on the client computer and configuration of the ODBC data source. This driver is used to allow Java programmers to build data-driver Java applications before the database vendor supplies a Type 3 or Type 4 driver. In general, this will not be used too much these days.</td>
</tr>
<tr>
<td>2</td>
<td><strong>Native-API, Part Java Drivers</strong> – enable JDBC programs to use database-specific APIs (normally written in C or C++) that allow client programs to access databases via the Java Native Interface. This driver translates JDBC into database-specific code. Reasons for use are similar to Type 1.</td>
</tr>
<tr>
<td>3</td>
<td><strong>JDBC-Net Pure Java Drivers</strong> – take JDBC requests and translate them into a network protocol that is not database specific. These requests are sent to a server, which translates the database requests into a database-specific protocol.</td>
</tr>
<tr>
<td>4</td>
<td><strong>Native-protocol Pure Java Drivers</strong> – convert JDBC requests to database-specific network protocols, so that Java programs can connect directly to a database.</td>
</tr>
</tbody>
</table>
## Some Popular JDBC Drivers

<table>
<thead>
<tr>
<th>RDBMS</th>
<th>JDBC Driver Name</th>
<th>Database URL format</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>com.mysql.jdbc.Driver</td>
<td>jdbc:mysql://hostname/databaseName</td>
</tr>
<tr>
<td>Oracle</td>
<td>oracle.jdbc.driver.OracleDriver</td>
<td>jdbc:oracle:thin@hostname:portnumber:databaseName</td>
</tr>
<tr>
<td>DB2</td>
<td>COM.ibm.db2.jdbc.net.DB2Driver</td>
<td>jdbc:db2:hostname:portnumber/databaseName</td>
</tr>
</tbody>
</table>
1. Application causes driver to be loaded

2. Application asks DriverManager for a connection to a particular DB. DriverManager asks all loaded drivers, and one of them responds with a connection.

3. DriverManager gives connection to the application.

4. Connection supplied by DriverManager is used by application to talk JDBC through the driver to the database.

How JDBC establishes a connection between your code and a database
Loading A JDBC Driver

• The first step (as illustrated in the previous slide) is to load a JDBC driver.

• If your application connects to several different types of databases, all of their respective drivers must be loaded.

• The Java statement to load a JDBC driver is:

```java
Class.forName(" JDBC Driver Class ");
```

• You don’t need to create an instance of the driver class. Simply getting the class loaded is enough. Each JDBC driver has a static initializer that is run when the class is loaded, and in that code the driver registers itself with the JDBC. The JDBC driver does about 90% of the work that is done in JDBC.
Establishing a Connection

- The second step involves the Java application requesting a connection to a database, using a string that looks like a URL as an argument.

- The JDBC library contains the class `java.sql.Connection` that knows how to use this string to guide it in its search for the correct database. As was shown in the table on page 7, the exact format of the pseudo-URL string will vary with each database, but it typically starts with “jdbc:” to indicate the protocol that will be used (just as “http:” indicates to a web server that you are using the hypertext transport protocol).

- The Java statement to connect to a database invokes the static method `getConnection(databaseURL)` in the `DriverManager` class:

```java
Connection connection = DriverManager.getConnection(url, username, password);
```

Optional parameters
Establishing a Connection (cont.)

- Behind the scenes, the DriverManager calls every JDBC driver that has been registered, and asks it if the URL is one that it can use to guide it to its database.
- If the URL is properly presented, it will be recognized by at least one of the drivers.
- The first driver to connect to its database with this URL, username, and password, will be used as the channel of communication.
- The application program gets back a Connection object (strictly speaking it gets an object that implements the Connection interface).
- The session has now been established and the connection is now used for communication between the application program and the database.
- You can think of the Connection object as cable linking your application program to the database.
Establishing a Connection (cont.)

- Connecting to a database is a time consuming operation. As a result, most databases have a way to share connections among several different processes. This arrangement is known as connection pooling.

- In summary:
  - Your application program knows which database it wants to talk to, and hence which database driver it needs to load.
  - The JDBC driver manager knows how to establish the JDBC end of a database connection.
  - The driver knows how to establish the database end of things.
  - The driver manager gives the application a connection into which you can pour standard SQL queries and get results.
Creating Statements

• If the `Connection` object can be viewed as a cable between your application program and the database, an object of `Statement` can be viewed as a cart that delivers SQL statements for execution by the database and brings the result back to the application program.

• Once a `Connection` object is created, you can create statements for executing SQL statements as follows:

```java
Statement statement = connection.createStatement();
```

• At this point, you’re now ready to begin issuing SQL commands to the database and getting back results. The table on the following page illustrates some of the methods contained in `java.sql.Connection`.
<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement createStatement()</td>
<td>Returns a statement object that is used to send SQL to the database.</td>
</tr>
<tr>
<td>PreparedStatement preparedStatement(String sql)</td>
<td>Returns an object that can be used for sending parameterized SQL statements.</td>
</tr>
<tr>
<td>CallableStatement.prepareCall(String sql)</td>
<td>Returns an object that can be used for calling stored procedures.</td>
</tr>
<tr>
<td>DatabaseMetaData.getMetaData()</td>
<td>Gets an object that supplied database configuration information.</td>
</tr>
<tr>
<td>boolean isClosed()</td>
<td>Reports whether the database is currently open or not.</td>
</tr>
<tr>
<td>void commit()</td>
<td>Makes all changes permanent since previous commit.rollback.</td>
</tr>
<tr>
<td>void rollback()</td>
<td>Undoes and discards all changes done since the previous commit/rollback.</td>
</tr>
</tbody>
</table>
### Selected Methods In `java.sql.Connection`

(Cont.)

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void setAutoCommit (boolean yn)</code></td>
<td>Restores/removes auto-commit mode, which does an automatic commit after each statement. The default case is AutoCommit is on.</td>
</tr>
<tr>
<td><code>void close()</code></td>
<td>Closes the connection and releases the JDBC resources for the connection.</td>
</tr>
<tr>
<td><code>boolean isReadOnly()</code></td>
<td>Retrieves whether this Connection object is in read-only mode.</td>
</tr>
<tr>
<td><code>void setReadOnly(boolean yn)</code></td>
<td>Puts this connection in read-only mode as a hint to the driver to enable database optimizations.</td>
</tr>
</tbody>
</table>
Creating Statements (cont.)

- The methods illustrated in the previous table are invoked on the Connection object returned by the JDBC driver manager.
- The connection is used to create a Statement object.
- The Statement object contains the methods that allow you to send the SQL statements to the database.
- Statement objects are very simple objects which allow you to send SQL statements as Strings.
- Here is how you would send a select query to the database:

```java
Statement myStmt = connection.createStatement();
ResultSet myResult;
myResult = myStmt.executeQuery( "SELECT * FROM bikes;" );
```

More on ResultSet later
Creating Statements (cont.)

• The different SQL statements have different return values. Some of them have no return value, some of them return the number of rows affected by the statement, and others return all the data extracted by the query.

• To handle these varied return results, you’ll need to invoke a different method depending on what type of SQL statement you are executing.

• The most interesting of these is the SELECT statement that returns an entire result set of data.

• The following table highlights some of the methods in java.sql.Statement to execute SQL statements.
Some Methods in java.sql.Statement to Execute SQL Statements

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>JDBC statement to use</th>
<th>Return Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td><code>executeQuery(String sql)</code></td>
<td>ResultSet</td>
<td>The return value will hold the data extracted from the database.</td>
</tr>
<tr>
<td>INSERT, UPDATE, DELETE, CREATE, DROP</td>
<td><code>executeUpdate(String sql)</code></td>
<td>int</td>
<td>The return value will give the count of the number of rows changed, or zero otherwise.</td>
</tr>
<tr>
<td>Stored procedure with multiple results</td>
<td><code>execute(String sql)</code></td>
<td>boolean</td>
<td>The return value is true if the first result is a ResultSet, false otherwise.</td>
</tr>
</tbody>
</table>
Putting It All Together – A Simple Example

• Let’s put all these pieces together and develop a Java application that will connect to our bikedb database, execute a query, and return the results.

• This application will show, in the simplest terms, how to load the JDBC driver, establish a connection, create a statement, have the statement executed, and return the results to the application.

• The code is shown on the next page with results on the following page.
// Very basic JDBC example showing loading of JDBC driver, establishing // a connection, creating a statement, executing a simple SQL query, and // displaying the results.
import java.sql.*;
public class SimpleJdbc {
    public static void main(String[] args)
        throws SQLException, ClassNotFoundException {
        // Load the JDBC driver
        Class.forName("com.mysql.jdbc.Driver");
        System.out.println("Driver loaded");
        // Establish a connection
        Connection connection = DriverManager.getConnection
            ("jdbc:mysql://localhost/bikedb", "root", "");
        System.out.println("Database connected");
        // Create a statement
        Statement statement = connection.createStatement();
        // Execute a statement
        ResultSet resultSet = statement.executeQuery
            ("select bikename,cost,mileage from bikes");
        // Iterate through the result set and print the returned results
        while (resultSet.next())
            System.out.println(resultSet.getString(1) + "\t" +
                resultSet.getString(2) + "\t" + resultSet.getString(3));
        // Close the connection
        connection.close();
    }
}
SimpleJdbc.java – Execution Results

Connection successfully established
Driver successfully loaded
JDBC driver version
Query results printed
Result Sets

- A ResultSet object is similar to a 2D array. Each call to `next()` moves to the next record in the result set. You must call `next()` before you can see the first result record, and it returns false when there are no more result records (this makes it quite convenient for controlling a while loop). (Also remember that the Iterator `next()` returns the next object and not a true/false value.)

- The class ResultSet has “getter” methods `getBlob()`, `getBigDecimal()`, `getDate()`, `getBytes()`, `getInt()`, `getLong()`, `getString()`, `getObject()`, and so on, for all the Java types that represent SQL types for a column name and column number argument. Look at the documentation for `java.sql.ResultSet` for a complete listing of the methods.
Result Sets (cont.)

- A default `ResultSet` object is not updatable and has a cursor that only moves forward.

- Many database drivers support scrollable and updatable `ResultSet` objects.
  - Scrollable result sets simply provide a cursor to move backwards and forwards through the records of the result set.
  - Updatable result sets provide the user with the ability to modify the contents of the result set and update the database by returning the updated result set. NOTE: Not all updates can be reflected back into the database. It depends on the complexity of the query and how the data in the result set was derived. In general, base relation attribute values can be modified through an updatable result set. We’ll see an example of this later.
### ResultSet Constants for Specifying Properties

<table>
<thead>
<tr>
<th>ResultSet static type constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_FORWARD_ONLY</td>
<td>Specifies that the ResultSet cursor can move only in the forward direction, from the first row to the last row in the result set.</td>
</tr>
<tr>
<td>TYPE_SCROLL_INSENSITIVE</td>
<td>Specifies that the ResultSet cursor can scroll in either direction and that the changes made to the result set during ResultSet processing are not reflected in the ResultSet unless the database is queried again.</td>
</tr>
<tr>
<td>TYPE_SCROLL_SENSITIVE</td>
<td>Specifies that the ResultSet cursor can scroll in either direction and that changes made to the result set during ResultSet processing are reflected immediately in the ResultSet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ResultSet static concurrency constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCUR_READ_ONLY</td>
<td>Specifies that the ResultSet cannot be updated (i.e. changes to it will not be reflected into the database).</td>
</tr>
<tr>
<td>CONCUR_UPDATABLE</td>
<td>Specifies that the ResultSet can be updated (i.e. changes to it will be reflected into the database using ResultSet update methods).</td>
</tr>
</tbody>
</table>
ResultSet Examples

• The following two examples clarify the various constants which can be applied to result sets (assume that connection is a valid Connection).

//creates a ResultSet which is scrollable, insensitive
//to changes by others and updatable.
Statement stmt = connection.createStatement(  
    (ResultSet.TYPE_SCROLL_INSENSITIVE,  
    ResultSet.CONCUR_UPDATABLE  );

//creates a ResultSet which is scrollable, sensitive
//to changes by others and updatable.
Statement stmt = connection.createStatement(  
    (ResultSet.TYPE_SCROLL_SENSITIVE,  
    ResultSet.CONCUR_UPDATABLE  );
Another Example

- In the previous example, notice that in the output, there was no information about what the columns represent. The output appears to be just data rather than information.

- A more sophisticated example, will access the database and use the metadata to provide more significance to the results.

- In the next example, we do just that by retrieving metadata from the database to help with the display of the result set.
// Displaying the contents of the bikes table.
import java.sql.Connection;
import java.sql.Statement;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.ResultSetMetaData;
import java.sql.SQLException;

public class DisplayBikes{
    // JDBC driver name and database URL
    static final String JDBC_DRIVER = "com.mysql.jdbc.Driver";
    static final String DATABASE_URL = "jdbc:mysql://localhost/bikedb2";

    // launch the application
    public static void main( String args[] ) {
        Connection connection = null; // manages connection
        Statement statement = null; // query statement

        // connect to database bikes and query database
        try {
            Class.forName( JDBC_DRIVER ); // load database driver class
        }
    }
}
// establish connection to database
connection =
   DriverManager.getConnection( DATABASE_URL, "root", "root" );

// create Statement for querying database
statement = connection.createStatement();

// query database
ResultSet resultSet = statement.executeQuery(
   "SELECT bikename, cost, mileage FROM bikes" );

// process query results
ResultSetMetaData metaData = resultSet.getMetaData();
int numberOfColumns = metaData.getColumnCount();
System.out.println( "Bikes Table of bikedb Database:" );
for ( int i = 1; i <= numberOfColumns; i++ )
   System.out.printf( "%20s\t", metaData.getColumnName( i ) );
System.out.println();
while ( resultSet.next() )
{
   for ( int i = 1; i <= numberOfColumns; i++ )
      System.out.printf( "%-20s\t", resultSet.getObject( i ) );
   System.out.println();}
System.out.println();
} // end while
} // end try
catch ( SQLException sqlException ) {
    sqlException.printStackTrace();
    System.exit( 1 );
} // end catch
catch ( ClassNotFoundException classNotFound ) {
    classNotFound.printStackTrace();
    System.exit( 1 );
} // end catch
finally {
    // ensure statement and connection are closed properly
    try {
        statement.close();
        connection.close();
    } // end try
    catch ( Exception exception ) {
        exception.printStackTrace();
        System.exit( 1 );
    } // end catch
} // end finally
} // end main

</tbody>
</table>
Note Regarding Static Method `forName`

- The database driver must be loaded before connecting to the database. The static method `forName` of class `Class` is used to load the class for the database driver.

- This method throws a checked exception of type `java.lang.ClassNotFoundException` if the class loader cannot locate the driver class.

- To avoid this exception, you need to include the `mysql-connector-java-5.1.7-bin.jar` in your program’s classpath when you execute the program.

- Copy the `mysql-connector-java-5.1.7-bin.jar` file to the JRE’s lib/ext directory. (www.mysql.com)
Querying the *bikedb* MySQL Database

- In this example, we’ll allow the user to enter any valid MySQL query into the Java application to query the bikes table of the bikedb database.

- The results of the query are returned in a JTable, using a TableModel object to provide the ResultSet data to the JTable.

- Class ResultSetTableModel performs the connection to the database and maintains the ResultSet.

- Class DisplayQueryResults creates the GUI and specifies an instance of class ResultSetTableModel to provide the data for the JTable.
// A TableModel that supplies ResultSet data to a JTable.
import java.sql.Connection;
import java.sql.Statement;
import java.sql.DriverManager;

The `PreparedStatement` Interface

- In the previous examples, once we established a connection to a particular database, it was used to send an SQL statement from the application to the database.

- The `Statement` interface is used to execute static SQL statements that contain no parameters.

- The `PreparedStatement` interface, which extends the `Statement` interface, is used to execute a precompiled SQL statement with or without `IN` parameters.

- Since the SQL statements are precompiled, they are extremely efficient for repeated execution.
A PreparedStatement object is created using the preparedStatement method in the Connection interface.

```java
Statement pstmt = connection.prepareStatement
    ("insert into bikes (bikename, size, color, cost, purchased, mileage) + values (? , ? , ? , ? , ? , ?)" );
```

Placeholders for the values that will be dynamically provided by the user.
The `PreparedStatement` Interface (cont.)

• As a subinterface of `Statement`, the `PreparedStatement` interface inherits all the methods defined in `Statement`. It also provides the methods for setting parameters in the object of `PreparedStatement`.

• These methods are used to set the values for the parameters before executing statements or procedures.

• In general, the set methods have the following signature:

```java
setX (int parameterIndex, X value);
```

where `X` is the type of parameter and `parameterIndex` is the index of the parameter in the statement.
The `PreparedStatement` Interface (cont.)

- As an example, the method

  ```java
  setString(int parameterIndex, String value)
  ```

  sets a String value to the specified parameter.

- Once the parameters are set, the prepared statement is executed like any other SQL statement where `executeQuery()` is used for SELECT statements and `executeUpdate()` is used for DDL or update commands.

- These two methods are similar to those found in the `Statement` interface except that they have no parameters since the SQL statements are already specified in the `preparedStatement` method when the object of a `PreparedStatement` is created.

    frame.setLocation((d.width - frame.getSize().width) / 2,
                      (d.height - frame.getSize().height) / 2);
    frame.setVisible(true);
}
Output from
FindBikeUsingPreparedStatement

Bike Name: Eddy Merckx Domo

Message:
Eddy Merckx Domo cost $5300
The **RowSet Interface** (cont.)

- Interface **RowSet** provides several set methods that allow the programmer to specify the properties needed to establish a connection (such as the database URL, user name, password, etc.) and a create a **Statement** (such as a query).

- Interface **RowSet** also provides several get methods that return these properties.

- More information on these methods can be found at: [http://java.sun.com/j2se/1.6.0/docs/api/javax/sql/RowSet.html](http://java.sun.com/j2se/1.6.0/docs/api/javax/sql/RowSet.html)
The **RowSet Interface** (cont.)

- **RowSet** is part of the `javax.sql` package.

- Although part of the Java 2 Standard Edition, the classes and interfaces of package `javax.sql` are most often used in the context of the Java 2 Platform Enterprise Edition (J2EE).

- We will get to some J2EE development later in the semester. You can learn more about J2EE at [www.java.sun.com/j2ee](http://www.java.sun.com/j2ee).
Using the `RowSet` Interface

- There are two types of `RowSet` objects—connected and disconnected.

- A connected `RowSet` object connects to the database once and remains connected until the application terminates.

- A disconnected `RowSet` object connects to the database, executes a query to retrieve the data from the database and then closed the connection. A program may change the data in a disconnected `RowSet` while it is disconnected. Modified data can be updated to the database after a disconnected `RowSet` reestablishes the connection with the database.
Using the \texttt{RowSet} Interface (cont.)

- J2SE 5.0 package \texttt{javax.sql.rowset} contains two subinterfaces of \texttt{RowSet} – \texttt{JdbcRowSet} and \texttt{CachedRowSet}.

- \texttt{JdbcRowSet}, a connected \texttt{RowSet}, acts as a wrapper around a \texttt{ResultSet} object, and allows programmers to scroll through and update the rows in the \texttt{ResultSet} object. Recall that by default, a \texttt{ResultSet} object is non-scrollable and read only – you must explicitly set the result-set type constant to \texttt{TYPE_SCROLL_INSENSITIVE} and set the result set concurrency constant to \texttt{CONCUR_UPDATEABLE} to make a \texttt{ResultSet} object scrollable and updatable.
Using the **RowSet Interface** (cont.)

- A `JdbcRowSet` object is scrollable and updatable by default.

- `CachedRowSet`, a disconnected `RowSet`, caches the data of a `ResultSet` in memory and disconnects from the database. Like `JdbcRowSet`, a `CachedRowSet` object is scrollable and updatable by default.

- A `CachedRowSet` is also serializable, so it can be passed between Java applications through a network.

- However, a `CachedRowSet` has a limitation – the amount of data that can be stored in memory is limited.

- There are three other subinterfaces in this package (FilteredRowSet, WebRowSet, and JoinRowSet).
Using the **RowSet Interface** (cont.)

- The code example on the next couple of pages illustrates the use of the RowSet interface.

- Notice that unlike the TableSet version in the previous set of notes, the connection is made and the query executed automatically.
