Form Processing and Business Logic

- XHTML forms enable web pages to collect data from users and send it to a web server for processing.
- Interaction of this kind between users and web servers is vital to e-commerce applications. Such capabilities allow users to purchase products, request information, send and receive web-based email, perform on-line paging and take advantage of various other online services.
- The XHTML document on the next few pages collects information from a user for the purposes of adding them to a mailing list.
- The PHP file on page 3 validates the data entered by the user through the form and “registers” them in the mailing list database.

form.html Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
  "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<!-- form.html -->
<!-- Form for use with the form.php program -->
```

This XHTML document generates the form that the user will submit to the server via form.php

```
<html xmlns = "http://www.w3.org/1999/xhtml">
  <head>
    <title>Sample form to take user input in XHTML</title>
  </head>
  <body>
```

```
    <h1>This is a sample registration form.</h1>
```

Please fill in all fields and click Register.

```
    <!-- post form data to form.php -->
    <form method = "post" action = "form.php">
      <img src = "images/user.gif" alt = "User" /><br />
      <span style = "color: blue">
        Please fill out the fields below.<br />
      </span>
      <!-- create four text boxes for user input -->
      <img src = "images/fname.gif" alt = "First Name" />
      <input type = "text" name = "fname" /><br />
```

```
<img src = "images/lname.gif" alt = "Last Name" />
<input type = "text" name = "lname" /><br />
<img src = "images/email.gif" alt = "Email" />
<input type = "text" name = "email" /><br />
<img src = "images/phone.gif" alt = "Phone" />
<input type = "text" name = "phone" /><br />
<span style = "font-size: 10pt">
  Must be in the form (555)555-5555</span>
<br /><br />
<img src = "images/downloads.gif"
  alt = "Products" /><br />
```

```
<span style = "color: blue">
  Which publication would you like information about?
</span><br />
```

```
<!-- create drop-down list containing magazine names -->
<select name = "magazine">
  <option>Velo-News</option>
  <option>Cycling Weekly</option>
  <option>Pro Cycling</option>
  <option>Cycle Sport</option>
    <option>RadSport</option>
    <option>Mirror du Cyclisme</option>
</select>
<br /><br />
```

```
<img src = "images/os.gif" alt = "Operating System" />
<br /><span style = "color: blue">
  Which operating system are you currently using?
<br /></span>
<!-- create five radio buttons -->
<input type = "radio" name = "os" value = "Windows XP"
  checked = "checked" />
  Windows XP
<input type = "radio" name = "os" value =
  "Windows 2000" />
  Windows 2000
<input type = "radio" name = "os" value =
  "Windows 98" />
  Windows 98<br />
<input type = "radio" name = "os" value = "Linux" />
  Linux

<input type = "radio" name = "os" value = "Other" />
  Other<br />

<!-- create a submit button -->
<input type = "submit" value = "Register" />
</form>
```

```
</body>
</html>
```

form.php Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```

```
<!-- form.php -->
```

```
<!-- Read information sent from form.html -->
```

```
<html xmlns = "http://www.w3.org/1999/xhtml">
```

```
<head>
```

```
<title>Form Validation</title>
```

```
</head>
```

```
<body style = "font-family: arial,sans-serif">
```

```
<?php
```

```
extract($_POST);
```

```
// determine whether phone number is valid and print an error message if not
```

```
if ( !ereg( "^\([0-9]{3}\)[0-9]{3}-[0-9]{4}$",
```

```
$phone ) ){
```

```
print( "<p><span style = \"color: red; font-size: 2em\">
```

```
INVALID PHONE NUMBER:</span><br />
```

```
A valid phone number must be in the form
```

```
<strong>(555)555-5555</strong><br />
```

```
<span style = \"color: blue\">
```

```
Click the Back button, enter a valid phone number and resubmit.<br /><br />
```

```
Thank You.</span></p></body></html> " );
```

```
die(); // terminate script execution
```

```
}
```

```
?>
```

Function extract (associativeArray) creates a variable-value pair corresponding to each key-value pair in the associative array \$_POST.

See page 17 for explanation of regular expressions.

Function die() terminates script execution. An error has occurred, no need to continue.

```

<p>Hi
  <span style = "color: blue"> <strong> <?php print( "$fname" ); ?> </strong> </span>.

Form Validation

Hi **Mark**. Thank you for completing the survey.
You have been added to the **Pro Cycling** mailing list.

The following information has been saved in our database:

Name	Email	Phone	OS
Mark Llewellyn	markl@cs.ucf.edu	(407)823-2790	Windows Vista

This is only a sample form. You have not been added to a mailing list.

After execution of form.php has verified correct entries made within the form.

User enters an improperly formatted telephone number in the form.

form.php issues error regarding improperly formatted telephone number.

How the Form Example Works

- The `action` attribute of the form element, indicates that when the user clicks the `Register` button, the form data will be posted to `form.php` for processing.
- Using `method = "post"` appends the form data to the browser request that contains the protocol (i.e., HTTP) and the requested resource's URL. Scripts located on the web server's machine (or accessible through the network) can access the form data sent as part of the request.
- Each of the form's input fields are assigned a unique name. When `Register` is clicked, each field's name and value are sent to the web server.
- Script `form.php` then accesses the value for each specific field through the global array `$_POST`.

How the Form Example Works (cont.)

- The superglobal arrays are associative arrays predefined by PHP that hold variable acquired from the user input, the environment, or the web server and are accessible in any variable scope.
 - If the information from the form had been submitted via the HTTP method `get`, then the superglobal array `$_GET` would contain the name-value pairs.
- Since the HTML form and the PHP script “communicate” via the name-value pairs, it is a good idea to make the XHTML object names meaningful so that the PHP script that retrieves the data is easier to understand.

Register_globals

- In PHP versions 4.2 and higher, the directive `register_globals` is set to `Off` by default for security reasons.
- Turning off `register_globals` means that all variables sent from an XHTML form to a PHP document now must be accessed using the appropriate superglobal array (either `$_POST` or `$_GET`).
- When this directive was turned `On`, as was the default case in PHP versions prior to 4.2, PHP created an individual global variable corresponding to each form field.

Validation of Form Generated Data

- The form example illustrates an important concept in the validation of user input. In this case, we simply checked the validity of the format of the telephone number entered by the client user.
- In general, it is crucial to validate information that will be entered into database or used in mailing lists. For example, validation can be used to ensure that credit-card numbers contain the proper number of digits before the numbers are encrypted to a merchant.
- In this case, the form.php script is implementing the **business logic** or **business rules** for our application.

Pattern Matching in PHP

- For powerful string comparisons (pattern matching), PHP provides functions `ereg` and `preg_match`, which use regular expressions to search a string for a specified pattern.
- Function `ereg` uses **Portable Operating System Interface (POSIX)** extended regular expressions.
 - POSIX-extended regular expressions are a standard to which PHP regular expression conform.
- Function `preg_match` provides **Perl-compatible regular expressions**.
- Perl-compatible regular expressions are more widely used than POSIX regular expressions. PHP's support for Perl-compatible regular expressions eases migration from Perl to PHP. The following examples illustrate these concepts.

expression.php - Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<!-- expression.php -->
<!-- Using regular expressions -->
<html xmlns = "http://www.w3.org/1999/xhtml">
  <head>
    <title>Regular expressions</title>
  </head>
  <body>
    <?php
      $search = "Now is the time";
      print( "Test string is: '$search'<br /><br />" );
      // call function ereg to search for pattern 'Now' in variable search
      if ( ereg( "Now", $search ) )
        print( "String 'Now' was found.<br />" );

      // search for pattern 'Now' in the beginning of the string
      if ( ereg( "^Now", $search ) )
        print( "String 'Now' found at beginning of the line.<br />" );

      // search for pattern 'Now' at the end of the string
      if ( ereg( "Now$", $search ) )
        print( "String 'Now' was found at the end of the line.<br />" );
```

^ matches at beginning
of a string

\$ matches at end of a
string

Uses a regular expression to match a word ending in "ow".

```
// search for any word ending in 'ow'
if ( ereg( "[[:<:]]([a-zA-Z]*ow)[[:>:]]", $search,
    $match ) )
    print( "Word found ending in 'ow': " .
        $match[ 1 ] . "<br />" );

// search for any words beginning with 't'
print( "Words beginning with 't' found: " );

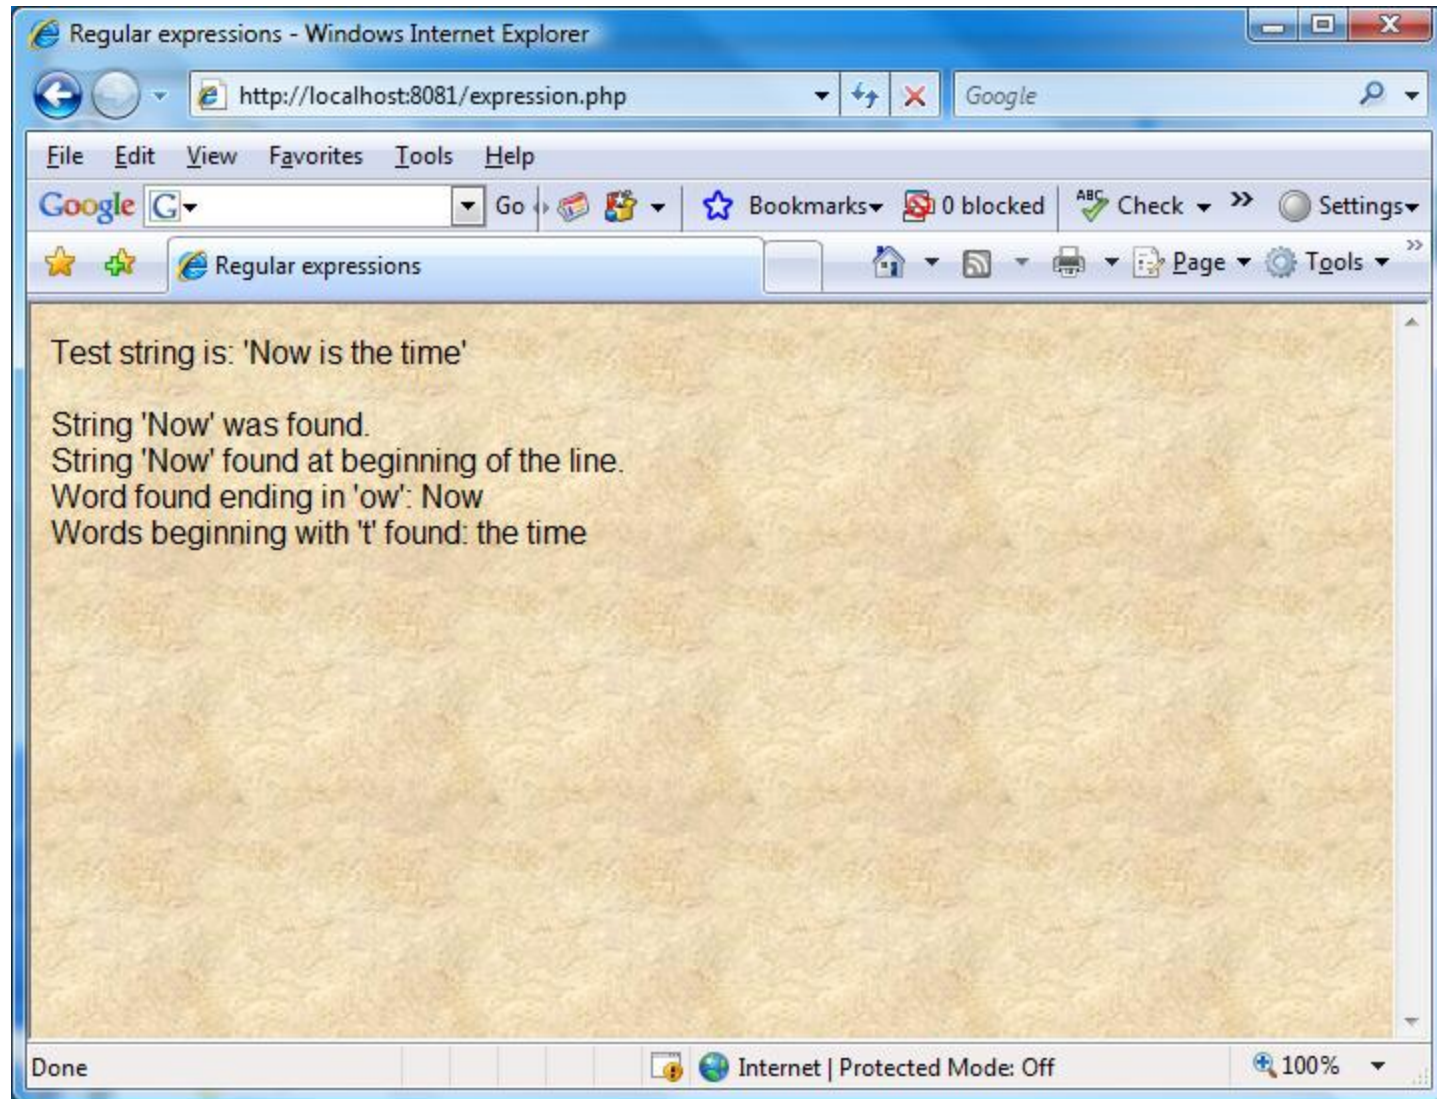

while ( eregi( "[[:<:]](t[[:alpha:]]+)[[:>:]]",
    $search, $match ) ) {
    print( $match[ 1 ] . " " );

    // remove the first occurrence of a word beginning
    // with 't' to find other instances in the string
    $search = ereg_replace( $match[ 1 ], "", $search );
}

print( "<br />" );
?>
</body>
</html>
```

Output From `expression.php` - Example

Verifying a Username and Password Using PHP

- It is often the case that a private website is created which is accessible only to certain individuals.
- Implementing privacy generally involves username and password verification.
- In the next example, we'll see an XHTML form that queries a user for a username and password. The fields `USERNAME` and `PASSWORD` are posted to the PHP script `verify.php` for verification.
 - For simplicity, data is not encrypted before sending it to the server.
 - For more information on PHP encryption functions visit: <http://www.php.net/manual/en/ref.mcrypt.php>.

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```

```
<!-- password.html -->
<!-- XHTML form sent to password.php for verification -->
```

```

Execution of password.html. Client-side XHTML form. User clicks on Enter button to submit and verify their information.

Execution of password.php to invalidate an attempted entry by a user.

How password.php Works

- The PHP script `password.php` verifies the client's username and password by querying a database. For this example, the “database” of usernames and passwords is just a text file (for simplicity). Existing users are validated against this file, and new users are appended to it.
- Whether we are dealing with a new user is determined by calling function `isset` to test if variable `$NewUser` has been set.
- When the user submits the `password.html` form to the server, they click either **Enter** or **New User** button. After calling function `extract`, either variable `$NewUser` or `$Enter` is created depending on which button was selected. If `$NewUser` has not been set, we assume the user clicked **Enter**.
