More Details on Establishing a Server Using Stream Sockets

• Step 1 is to create a `ServerSocket` object.

• Invoking a `ServerSocket` constructor such as,

```java
ServerSocket server =
    new ServerSocket (portNumber, queueLength);
```

registers an available TCP port number and specifies the number of clients that can wait to connect to the server (i.e., the queue length).
More Details on Establishing a Server Using Stream Sockets (cont.)

• The port number is used by the clients to locate the server application on the server computer. This is often called the handshake point.

• If the queue is full, the server refuses client connections.

• The constructor establishes the port where the server waits for connections from clients – a process known as binding the server to the port.

• Each client will ask to connect to the server on this port. Only one application at a time can be bound to a specific port on the server.
More Details on Establishing a Server Using Stream Sockets (cont.)

- Port numbers can be between 0 and 65,535. Most OS reserve port numbers below 1024 for system services such as email, and Internet servers. Generally, these ports should not be specified as connection ports in user programs. In fact, some OS require special access privileges to bind to port numbers below 1024.

- Programs manage each client connection with a Socket object.
More Details on Establishing a Server Using Stream Sockets (cont.)

- In Step 2, the server listens indefinitely (is said to block) for an attempt by a client to connect. To listen for a client connection, the program calls `ServerSocket` method `accept`, as in,

```java
Socket connection = server.accept();
```

which returns a `Socket` when a connection with a client is established.

- The `Socket` allows the server to interact with the client.

- The interactions with the client actually occur at a different server port from the handshake port. This allows the port specified in Step 1 to be used again in a multi-threaded server to accept another client connection. We’ll see an example of this later in this set of notes.
More Details on Establishing a Server Using Stream Sockets (cont.)

• In **Step 3**, the `OutputStream` and `InputStream` objects that enable the server to communicate with the client by sending and receiving bytes are established.

• The server sends information to the client via an `OutputStream` and received information from the client via an `InputStream`.

• The server invokes the method `getOutputStream` on the `Socket` to get a reference to the `Socket`’s `OutputStream` and invokes method `getInputStream` on the `Socket` to get a reference to the `Socket`’s `InputStream`. 
More Details on Establishing a Server Using Stream Sockets (cont.)

- If primitive types or serializable types (like String) need to be sent rather than bytes, wrapper classes are used to wrap other stream types around the OutputStream and InputStream objects associated with the Socket.

```java
ObjectInputStream input =
    new(ObjectInputStream(connection.getInputStream()));

ObjectOutputStream output =
    new(ObjectOutputStream(connection.getOutputStream()));
```
More Details on Establishing a Server Using Stream Sockets (cont.)

• The beauty of establishing these relationships is that whatever the server writes to the ObjectOutputStream is set via the OutputStream and is available at the client’s InputStream, and whatever the client writes to its OutputStream (with a corresponding ObjectOutputStream) is available via the server’s InputStream.

• The transmission of the data over the network is seamless and is handled completely by Java.
More Details on Establishing a Server Using Stream Sockets (cont.)

• With Java’s multithreading, you can create multithreaded servers that can manage many simultaneous connections with many clients.

• A multithreaded server can take the Socket returned by each call to accept and create a new thread that manages network I/O across that Socket.

  – Alternatively, a multithreaded server can maintain a pool of threads (a set of already existing threads) ready to manage network I/O across the new Sockets as they are created. In this fashion, when the server receives a connection, it need not incur the overhead of thread creation. When the connection is closed, the thread is returned to the pool for reuse.
More Details on Establishing a Server Using Stream Sockets (cont.)

- **Step 4** is the processing phase, in which the server and client communicate via the `OutputStream` and `InputStream` objects.

- **In Step 5**, when the transmission is complete, the server closes the connection by invoking the `close` method on the streams and on the `Socket`. 
More Details on Establishing a Client Using Stream Sockets

- **Step 1** is to create a `Socket` object to connect to the server. The `Socket` constructor established the connection with the server.

- For example, the statement

  ```java
  Socket connection = new Socket(serverAddress, port);
  ```

  uses the `Socket` constructor with two arguments – the server’s address and the port number.

- If the connection attempt is successful, this statement returns a `Socket`. 
More Details on Establishing a Client Using Stream Sockets (cont.)

- If the connection attempt fails, an instance of a subclass of IOException, since so many programs simply catch IOException.

- An UnknownHostException occurs specifically when the system is unable to resolve the server address specified in the call to the Socket constructor to a corresponding IP address.
More Details on Establishing a Client Using Stream Sockets (cont.)

• In **Step 2**, the client uses Socket methods `getInputStream` and `getOutputStream` to obtain references to the Socket’s InputStream and OutputStream.

• If the server is sending information in the form of actual types (not byte streams) the client should receive the information in the same format. Thus, if the server sends values with an `ObjectOutputStream`, the client should read those values with an `ObjectInputStream`. 
More Details on Establishing a Client Using Stream Sockets (cont.)

- **Step 3** is the same as in the server, where the client and the server communicate via `InputStream` and `OutputStream` objects.

- In **Step 4**, the client closes the connection when the transmission is complete by invoking the close method on the streams and on the `Socket`.

- The client must determine when the server is finished sending information so that it can call `close` to close the `Socket` connection.

- For example, the `InputStream` method `read` returns the value -1 when it detects end-of-stream (also called EOF). If an `ObjectInputStream` is used to read information from the server, an `EOFException` occurs when the client attempts to read a value from a stream on which end-of-stream is detected.

Using Java’s High-level Networking Capabilities

• As we saw earlier, the TCP and UDP protocols are at the transport layer within the Internet Reference Model. As far as Java is concerned, these provide “low-level” networking capability.

• Java also provides application layer networking protocol capabilities to allow for communication between applications.

• In the examples we have seen so far, it was the developer’s responsibility to establish a connection between the client and the server (in the case of the UDP protocol, its more a process of establishing the sockets since there is no connection between the client and the server in this protocol).
Using Java’s High-level Networking Capabilities (cont.)

• The next two examples illustrate Java’s application layer capabilities which remove the responsibility of establishing the network connection from the developer.

• The first example relies on a Web browser to establish the communication link to a Web server. (This one uses an applet to open a specific URL. Using a URL as an argument to the `showDocument` method of interface `AppletContext`, causes the browser in which the applet is executing to display that resource.)

• The second example uses a `JOptionPane` to perform the connection. (This example is an application that opens and reads a file on a specified web server, hence it acts as a simple web browser.)
Example 1 – SiteSelector Applet

```html
<html>
<title>Site Selector</title>
<body>
  <applet code = "SiteSelector.class" width = "300" height = "75">
    <param name = "title0" value = "Java Home Page">
    <param name = "location0" value = "http://www.java.sun.com/">
    <param name = "title1" value = "CNT 47174 Home Page">
    <param name = "location1" value = "http://www.cs.ucf.edu/courses/cnt4714/spr2009">
    <param name = "title2" value = "World Cycling News">
    <param name = "location2" value = "http://www.cyclingnews.com/">
    <param name = "title3" value = "Formula 1 News">
    <param name = "location3" value = "http://www.formula1.com/">
  </applet>
</body>
</html>
```

HTML document to load the SiteSelector Applet

import javax.swing.event.ListSelectionEvent;
import javax.swing.event.ListSelectionListener;

public class SiteSelector extends JApplet
{
    private HashMap< Object, URL > sites; // site names and URLs
    private ArrayList< String > siteNames; // site names
    private JList siteChooser; // list of sites to choose from

    // read HTML parameters and set up GUI
Example 1 – SiteSelector Applet (cont.)

```java
public void init()
{
    sites = new HashMap< Object, URL >();  // create HashMap
    siteNames = new ArrayList< String >();  // create ArrayList
    // obtain parameters from HTML document
    getSitesFromHTMLParameters();
    // create GUI components and layout interface
    add( new JLabel( "Choose a site to browse" ), BorderLayout.NORTH );
    siteChooser = new JList( siteNames.toArray() );  // populate JList
    siteChooser.addListSelectionListener(
        new ListSelectionListener() // anonymous inner class
            {
                // go to site user selected
                public void valueChanged( ListSelectionEvent event )
                {
                    // get selected site name
                    Object object = siteChooser.getSelectedValue();
                    // use site name to locate corresponding URL
                    URL newDocument = sites.get( object );
                    // get applet container
                    AppletContext browser = getAppletContext();
                    // tell applet container to change pages
                    browser.showDocument( newDocument );
                } // end method valueChanged
            } // end anonymous inner class
    ); // end call to addListSelectionListener
}
```
Example 1 – SiteSelector Applet (cont.)

```
add( new JScrollPane( siteChooser ), BorderLayout.CENTER );
} // end method init
// obtain parameters from HTML document
private void get SitesFromHTMLParameters()
{
  String title; // site title
  String location; // location of site
  URL url; // URL of location
  int counter = 0; // count number of sites
  title = getParameter( "title" + counter ); // get first site title
  // loop until no more parameters in HTML document
  while ( title != null )
  {
    // obtain site location
    location = getParameter( "location" + counter );
    try // place title/URL in HashMap and title in ArrayList
    {
      url = new URL( location ); // convert location to URL
      sites.put( title, url ); // put title/URL in HashMap
      siteNames.add( title ); // put title in ArrayList
    }
    catch ( MalformedURLException urlException )
    {
      urlException.printStackTrace();
    }
    counter++;
    title = getParameter( "title" + counter ); // get next site title
  } // end while
} // end method
```

    private JEditorPane contentsArea; // to display Web site
    // set up GUI
    public ReadServerFile()
    {
        super( "Simple Web Browser" );
    }
// create enterField and register its listener
enterField = new JTextField( "Enter file URL here" );
enterField.addActionListener(
    new ActionListener()
    {
        // get document specified by user
        public void actionPerformed( ActionEvent event )
        {
            getThePage( event.getActionCommand() );
        } // end method actionPerformed
    } // end inner class
); // end call to addActionListener
add( enterField, BorderLayout.NORTH );

contentsArea = new JEditorPane(); // create contentsArea
contentsArea.setEditable( false );
contentsArea.addHyperlinkListener(
    new HyperlinkListener()
    {
        // if user clicked hyperlink, go to specified page
        public void hyperlinkUpdate( HyperlinkEvent event )
        {
            if ( event.getEventType() == HyperlinkEvent.EventType.ACTIVATED )
                getThePage( event.getURL().toString() );
        } // end method hyperlinkUpdate
    } // end inner class
); // end call to addHyperlinkListener
Example 2 – ReadServerFile Application (cont.)

```java
add( new JScrollPane( contentsArea ), BorderLayout.CENTER );
setSize( 400, 300 ); // set size of window
setVisible( true ); // show window
} // end ReadServerFile constructor

// load document
private void getThePage( String location )
{
    try // load document and display location
    {
        contentsArea.setPage( location ); // set the page
        enterField.setText( location ); // set the text
    } // end try
    catch ( IOException ioException )
    {
        JOptionPane.showMessageDialog( this, "Error retrieving specified URL", "Bad URL", JOptionPane.ERROR_MESSAGE );
    } // end catch
} // end method getThePage
} // end class ReadServerFile

// ReadServerFileTest.java
// Create and start a ReadServerFile.
import javax.swing.JFrame;

public class ReadServerFileTest
{
    public static void main( String args[] )
    {
        ReadServerFile application = new ReadServerFile();
        application.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
    } // end main
} // end class ReadServerFileTest
```

Driver class to execute ReadServerFile application
Secure Sockets Layer (SSL)

- Most e-business uses SSL for secure on-line transactions.
- SSL does not explicitly secure transactions, but rather secures connections.
- SSL implements public-key technology using the RSA algorithm (developed in 1977 at MIT by Ron Rivest, Adi Shamir, and Leonard Adleman) and digital certificates to authenticate the server in a transaction and to protect private information as it passes from one part to another over the Internet.
- SSL transactions do not require client authentication as most servers consider a valid credit-card number to be sufficient for authenticating a secure purchase.
How SSL Works

• Initially, a client sends a message to a server.

• The server responds and sends its digital certificate to the client for authentication.

• Using public-key cryptography to communicate securely, the client and server negotiate session keys to continue the transaction.

• Once the session keys are established, the communication proceeds between the client and server using the session keys and digital certificates.

• Encrypted data are passed through TCP/IP (just as regular packets over the Internet). However, before sending a message with TCP/IP, the SSL protocol breaks the information into blocks and compresses and encrypts those blocks.
How SSL Works (cont.)

• Once the data reach the receiver through TCP/IP, the SSL protocol decrypts the packets, then decompresses and assembles the data. It is these extra processes that provide an extra layer of security between TCP/IP and applications.

• SSL is used primarily to secure point-to-point connections using TCP/IP rather than UDP/IP.

• The SSL protocol allows for authentication of the server, the client, both, or neither. Although typically in Internet SSL sessions only the server is authenticated.

</tbody>
</table>
Details Of The SSL Protocol

• Use the diagram on the previous page to index the steps.

1. **Client hello.** The client sends the server information including the highest level of SSL it supports and a list of the cipher suites it supports including cryptographic algorithms and key sizes.

2. **Server hello.** The server chooses the highest version of SSL and the best cipher suite that both the client and server support and sends this information to the client.
Details Of The SSL Protocol (cont.)

3. **Certificate.** The server sends the client a certificate or a certificate chain. Optional but used whenever server authentication is required.

4. **Certificate Request.** If the server needs to authenticate the client, it sends the client a certificate request. In most Internet applications this message is rarely sent.

5. **Server key exchange.** The server sends the client a server key exchange message when the public key information sent in (3) above is not sufficient for key exchange.
Details Of The SSL Protocol (cont.)

6. **Server hello done.** The server tells the client that it is finished with its initial negotiation messages.

7. **Certificate.** If the server requests a certificate from the client in (4), the client sends its certificate chain, just as the server did in (3).

8. **Client key exchange.** The client generates information used to create a key to use for symmetric encryption. For RSA, the client then encrypts this key information with the server’s public key and sends it to the server.
Details Of The SSL Protocol (cont.)

9. **Certificate verify.** This message is sent when a client presents a certificate as above. Its purpose is to allow the server to complete the process of authenticating the client. When this message is used, the client sends information that it digitally signs using a cryptographic hash function. When the server decrypts this information with the client’s public key, the server is able to authenticate the client.

10. **Change to encrypted mode.** The client sends a message telling the server to change to encrypted mode.

11. **Finished.** The client tells the server that it is ready for secure data communication to begin.
Details Of The SSL Protocol (cont.)

12. Change to encrypted mode. The server sends a message telling the client to switch to encrypted mode.

13. Finished. The server tells the client that it is ready for secure data communication to begin. This marks the end of the SSL handshake.

14. Encrypted data. The client and the server communicate using the symmetric encryption algorithm and the cryptographic hash function negotiated in (1) and (2), and using the secret key that the client sent to the server in (8).

15. Close messages. At the end of the connection, each side will send a close_notify message to inform the peer that the connection is closed.
Java Secure Socket Extension (JSSE)

- SSL encryption has been integrated into Java technology through the Java Secure Socket Extension (JSSE). JSSE has been an integral part of Java (not a separately loaded extension) since version 1.4.
- JSSE provides encryption, message integrity checks, and authentication of the server and client.
- JSSE uses keystores to secure storage of key pairs and certificates used in PKI (Public Key Infrastructure which integrates public-key cryptography with digital certificates and certificate authorities to authenticate parties in a transaction.)
- A truststore is a keystore that contains keys and certificates used to validate the identities of servers and clients.
Java Secure Socket Extension (JSSE) (cont.)

- Using secure sockets in Java is very similar to using the non-secure sockets that we have already seen.
- JSSE hides the details of the SSL protocol and encryption from the programmer entirely.
- The final example in this set of notes involves a client application that attempts to logon to a server using SSL.
- **NOTE:** Before attempting to execute this application, look at the code first and then go to page 45 for execution details. This application will not execute correctly unless you follow the steps beginning on page 45.

            // create SSLSocket from factory
            SSLSocket socket = (SSLSocket) socketFactory.createSocket("localhost", 7070);
            // create PrintWriter for sending login to server
            PrintWriter output = new PrintWriter(new OutputStreamWriter(socket.getOutputStream()));
            // prompt user for user name
            String userName = JOptionPane.showInputDialog(null, "Enter User Name:" );
            // send user name to server
            output.println(userName);
        }
    }
}
String password = JOptionPane.showInputDialog( null, "Enter Password:" );
// send password to server
output.println( password );
output.flush();
// create BufferedReader for reading server response
BufferedReader input = new BufferedReader(
    new InputStreamReader( socket.getInputStream () ) );
// read response from server
String response = input.readLine();
// display response to user
JOptionPane.showMessageDialog( null, response );
// clean up streams and SSLSocket
output.close();
input.close();
socket.close();
} // end try
// handle exception communicating with server
catch ( IOException ioException ) {
    ioException.printStackTrace();
} // exit application
finally {
    System.exit( 0 );
} // end LoginClient constructor
// execute application
public static void main( String args[] )
{
    new LoginClient();
}
Creating Keystore and Certificate

• Before you can execute the LoginServer and LoginClient application using SSL you will need to create a keystore and certificate for the SSL to operate correctly.

• Utilizing the keytool (a key and certificate management tool) in Java generate a keystore and a certificate for this server application. See the next slide for an example.

• We’ll use the same keystore for both the server and the client although in reality these are often different. The client’s truststore, in real-world applications, would contain trusted certificates, such as those from certificate authorities (e.g. VeriSign (www.verisign.com), etc.).
Creating Keystore and Certificate

Note requirements for password.
Creating Keystore and Certificate

Viewing the keystore contents after its creation.

Notice the entry type is keyEntry which means that this entry has a private key associated with it.
Creating Keystore and Certificate

Export the certificate into a certificate file.

Contents of the certificate.
Creating Keystore and Certificate

Import the certificate into a new truststore.

```plaintext
C:\Program Files\Java\jdk1.6.0_10\bin>keytool -import -alias sslcertificate -file mycert.cer -keystore truststore
Enter keystore password:
Re-enter new password:
Owner: CN=Mark Llewellyn, OU=UCF CS Dept, O=UCF, L=Orlando, ST=Florida, C=US
Issuer: CN=Mark Llewellyn, OU=UCF CS Dept, O=UCF, L=Orlando, ST=Florida, C=US
Serial number: 498b4236
Valid from: Thu Feb 05 14:47:02 EST 2009 until: Wed May 06 15:47:02 EDT 2009
Certificate fingerprints:
Signature algorithm name: SHA1withDSA
Version: 3
Trust this certificate? [no] yes
Certificate was added to keystore

C:\Program Files\Java\jdk1.6.0_10\bin>
```
Creating Keystore and Certificate

View the contents of the truststore.

Note that the entry type is trustedCertEntry, which means that a private key is not available for this entry. It also means that this file is not suitable as a KeyManager's keystore.
Launching the Secure Server

• Now you are ready to start the server executing from a command prompt…
• Once started, the server simply waits for a connection from a client. The example below illustrates the server after waiting for several minutes.

Start the SSL Server executing with this command where you replace this password with the password you used when you set-up the keystore.
Launching the SSL Client

- Start a client application executing from a new command window…
- Once the client establishes communication with the server, the authentication process begins.

Start the SSL Client application executing with this command where you replace this password with the password you used when you set-up the keystore. Since we are using the same keystore for the server and the client…these will be the same.
User enters username and password which are sent to the server.

Authentication successful – user is logged on.
User enters username and password which are sent to the server. In this case the user enters an incorrect password.

Authentication not successful – user is not logged on.
Multithreaded Socket Client/Server Example

- As a culminating example of networking and multi-threading, I’ve put together a rudimentary multi-threaded socket-based TicTacToe client/server application. The code is rather lengthy and there isn’t really anything in it that we haven’t already seen in the earlier sections of the notes. However, I did want you to see a somewhat larger example that utilizes both sockets and threading in Java. The code is on the course web page so try it out.

- This application is a multithreaded server that will allow two client’s to play a game of TicTacToe run on the server.

- To execute, open three command windows, start one server and two clients (in separate windows).

- The following few pages contain screen shots of what you should see when executing this code.
Start server running…
Indicate to first player that server is waiting for another player thread to connect.

Start first player thread
Player X is notified by server that another player has connected and they can make their move.

Second player thread connects to server and is ready to play.

Server completes connection for second player. Notifies Player X that they can make their move.
Player X makes a move by placing an “X” marker in location 4 of the game board.

Server validates move made by Player X, records board configuration and notifies Player O that they can move and redraws the board for Player O.

Player O sees the move made by Player X and is now ready to make a move.

Player X makes a move by placing an “X” marker in location 4 of the game board.
Although Player X has won the game, this server is too dumb to know this and allows the game to continue.

Player O is notified that Player X has made a move and is graphically shown the updated board layout. Server indicates Player O is now able to make their move. No indication is given that the game is technically over.

Although Player X has won the game, this server is too dumb to know this and allows the game to continue.
