Computer Science Division
University of Central Florida

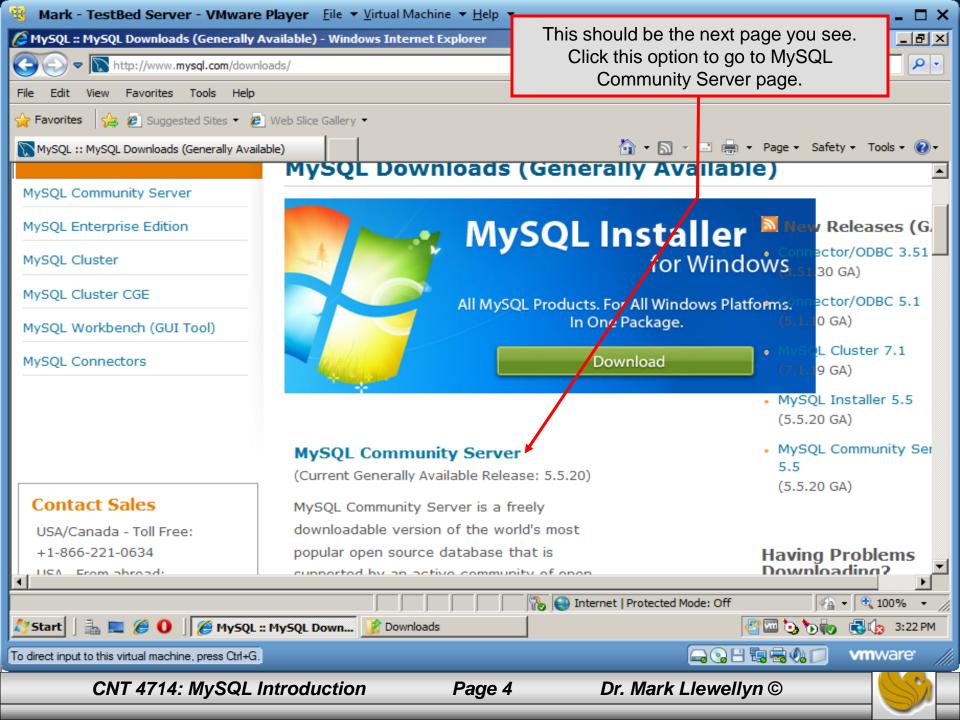

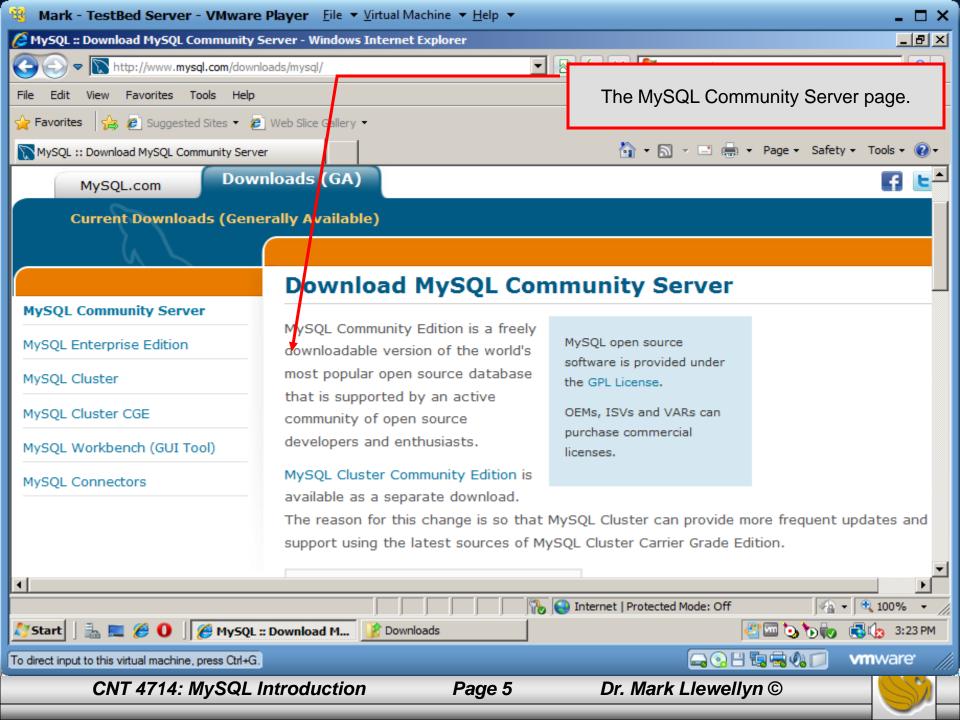

#### MySQL RDBMS

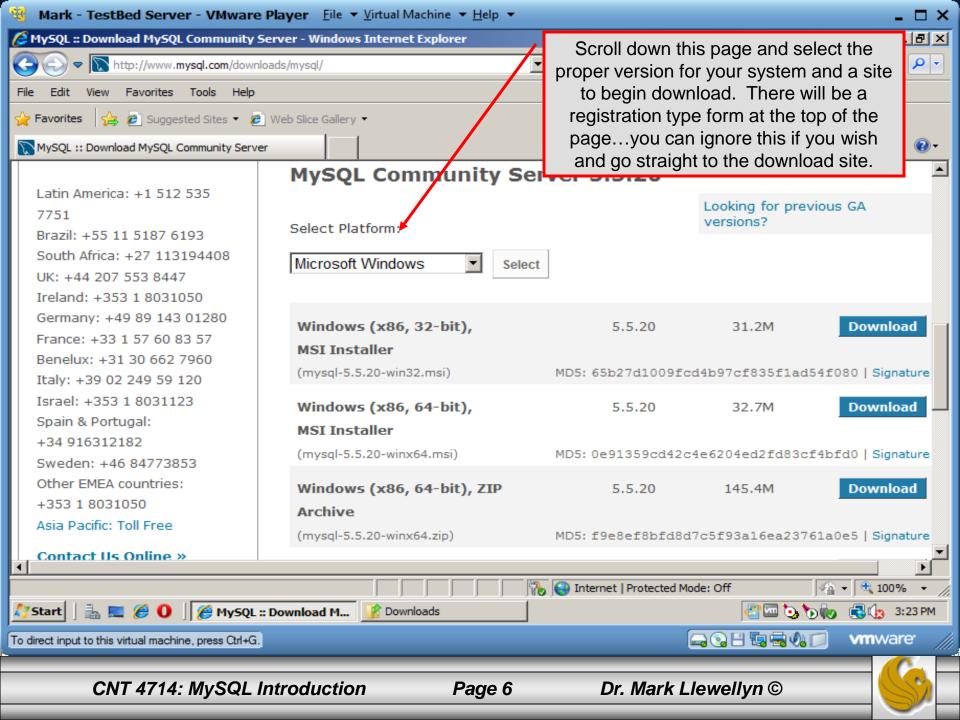

- MySQL is a database server (although it does come with a set of simple client programs). The current stable version is 5.5.20 and can be downloaded from <a href="www.mysql.com">www.mysql.com</a>.
- It is typically used in thin client environments. In other words, it is used in client-server systems where the bulk of the processing and storage takes place on the server, and the client is little more than a dumb terminal.
- MySQL performs multithreaded processing, which means that multiple clients are allowed to connect to it and run queries simultaneously. This makes MySQL extremely fast and well suited to client-server environments such as Web sites and other environments that process numerous transactions for multiple users.

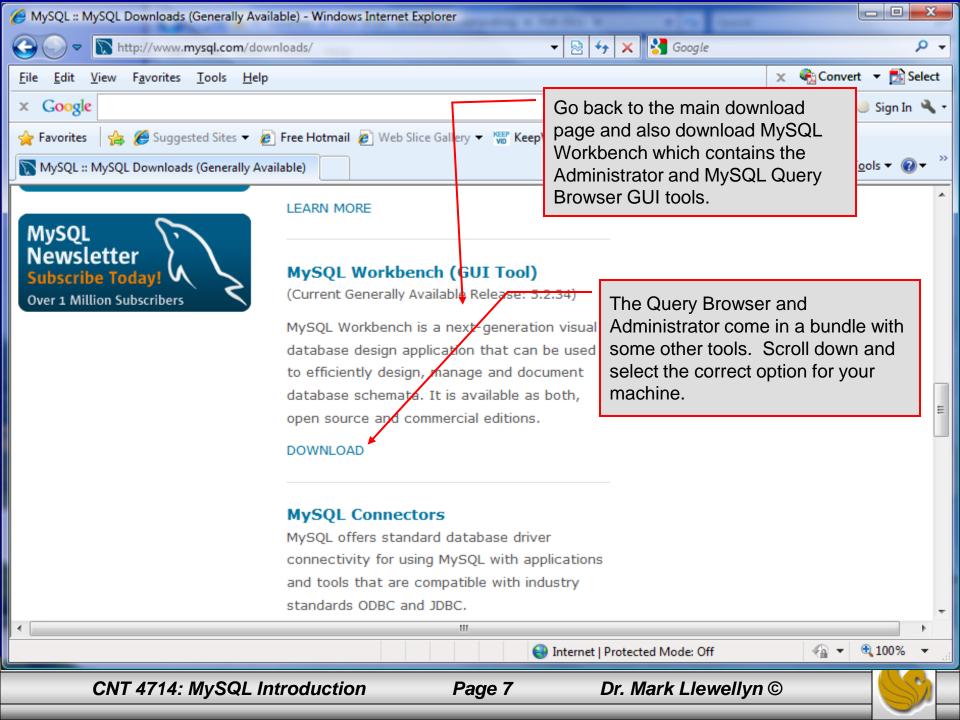

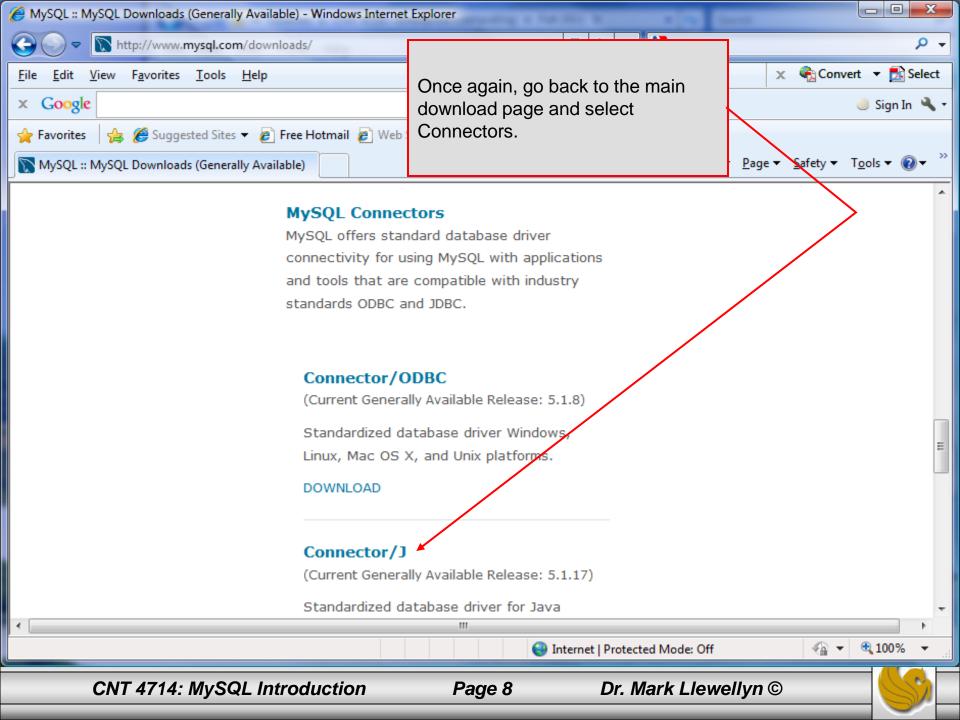

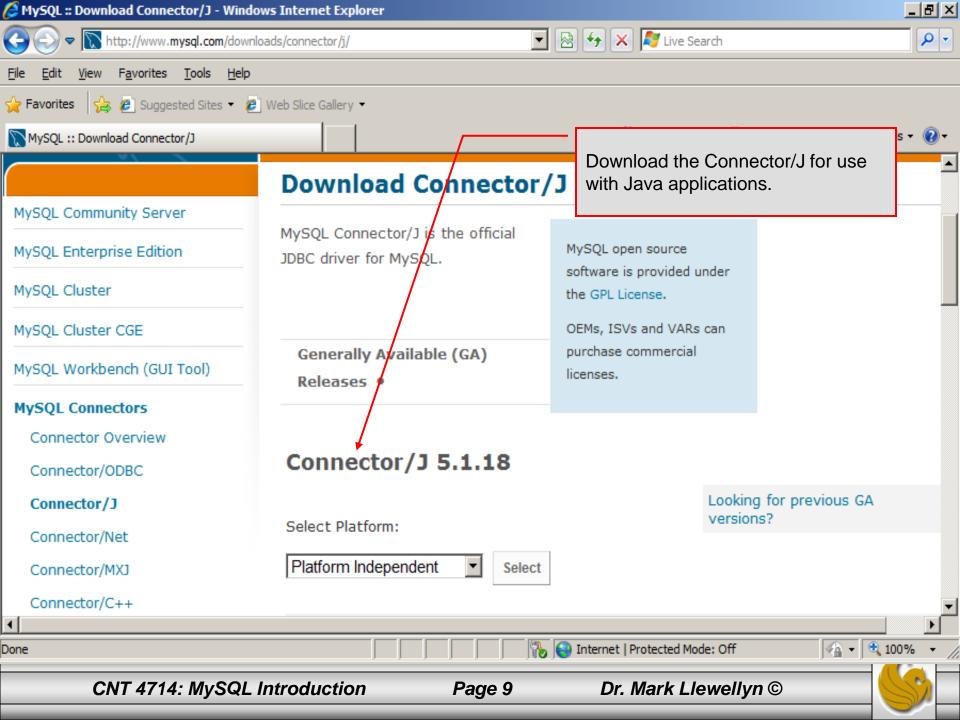

# Installing MySQL 5.5.20

- Once you've got MySQL downloaded, go through the installation process. It may vary somewhat depending on platform.
- I've illustrated the basic install on Windows Vista over the next few pages, just to give you an idea of what you should be seeing.

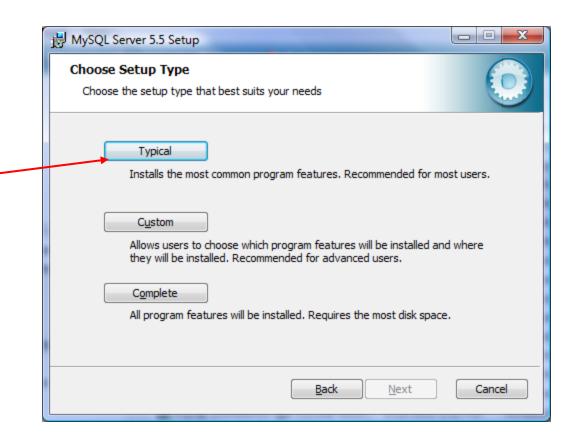

# Installing MySQL 5.5.20

- Once the Window installer is running you should see the following window appear:
- Click Next and accept the terms on the next window.

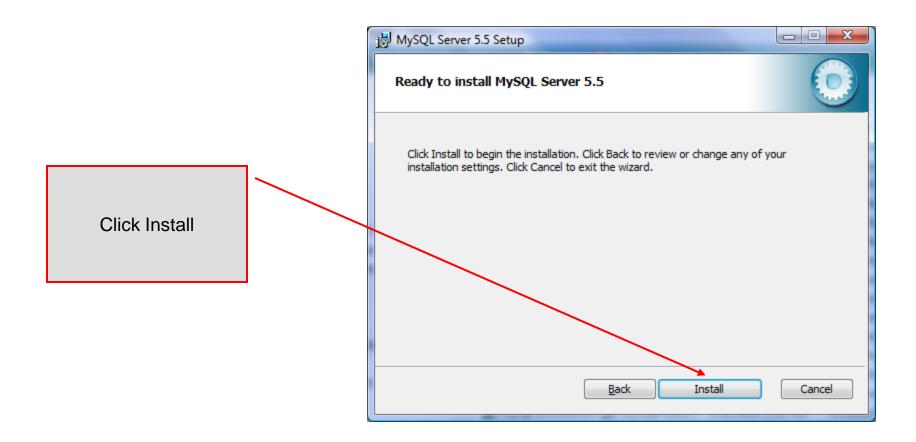

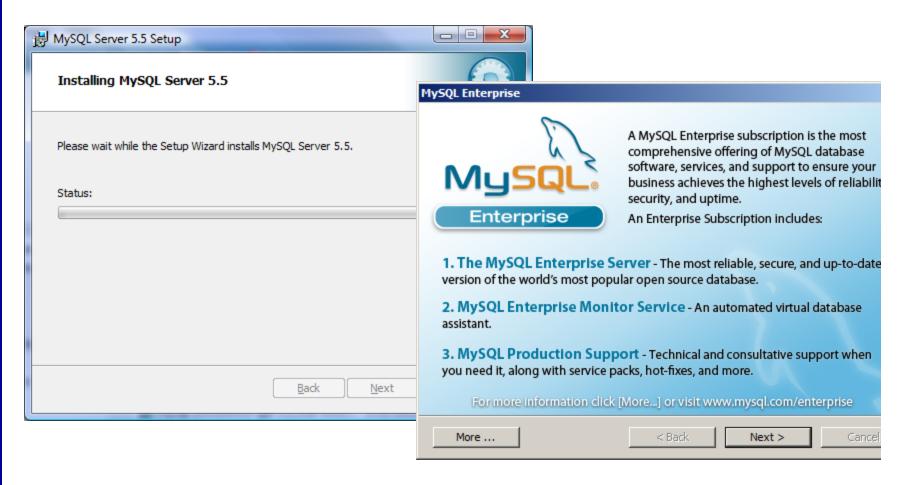

Your choice here. For this course, a typical set-up will be fine.

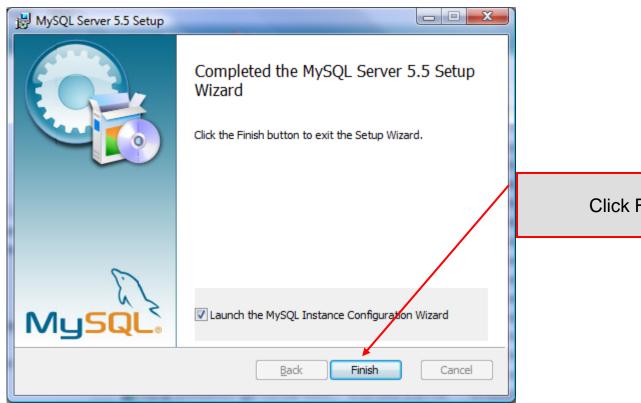

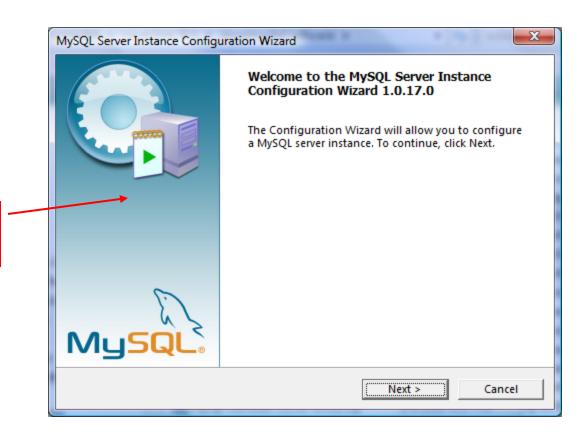

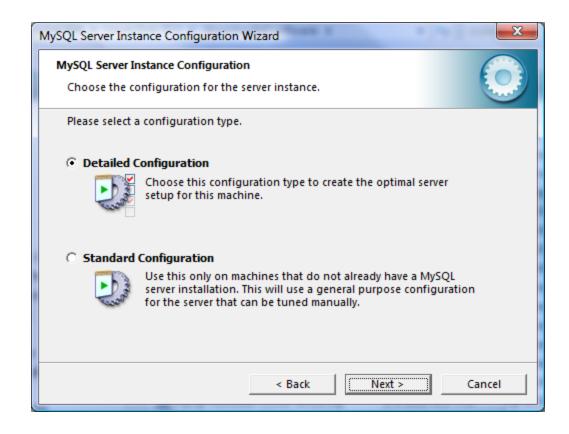

Click Finish

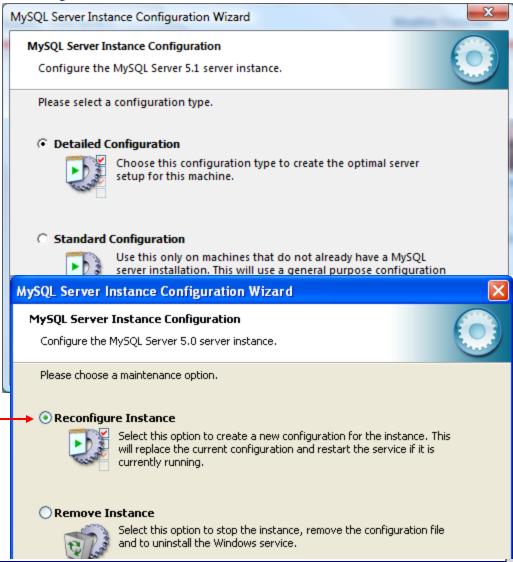

Initial server configuration window

Your choice here. If you are not sure if there is already a MySQL server on your machine, choose the detailed configuration setting.

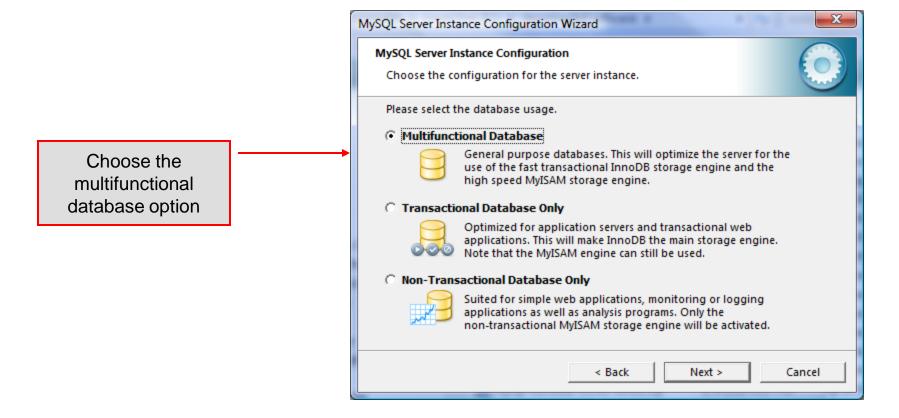

If you already have an instance of a MySQL server on your machine, you'll see this screen first, followed by the one above. Select reconfigure instance.

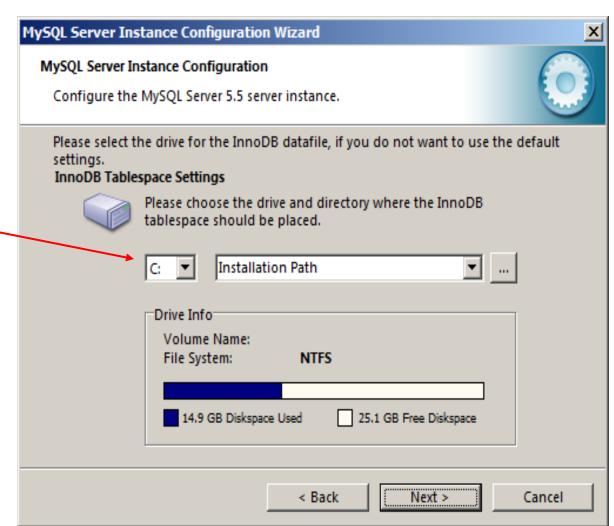

Choose the developer machine option

Choose the installation path to keep InnoDB tables in same area as other MySQL files

Select manual setting

default is 15, I set mine

to 10, but you can use

any number you would

like, but pick something

greater than 3 or 4.

for this option. The

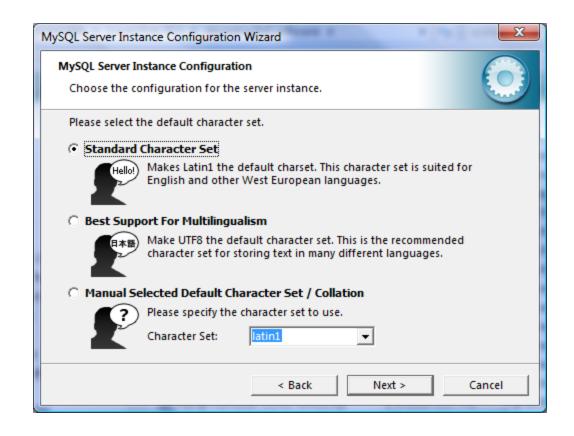

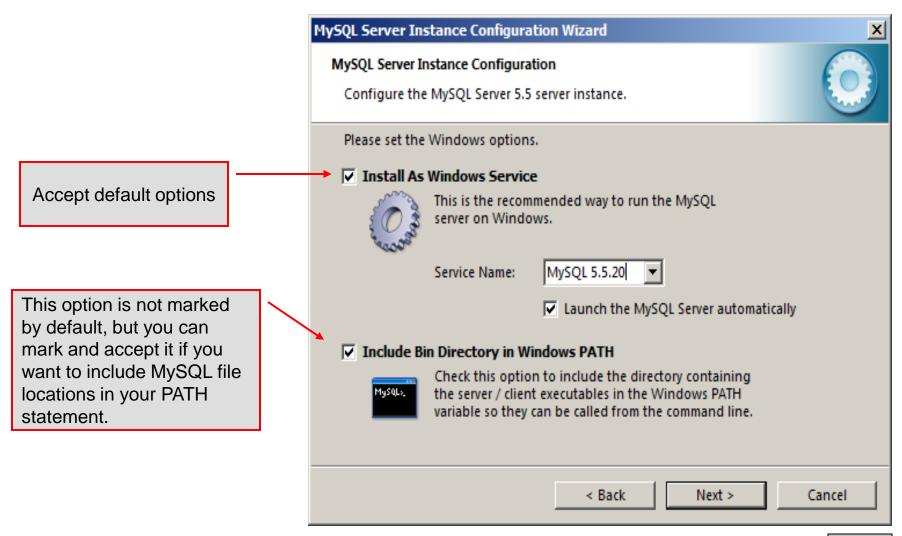

Accept all

defaults in this window

Your choice again

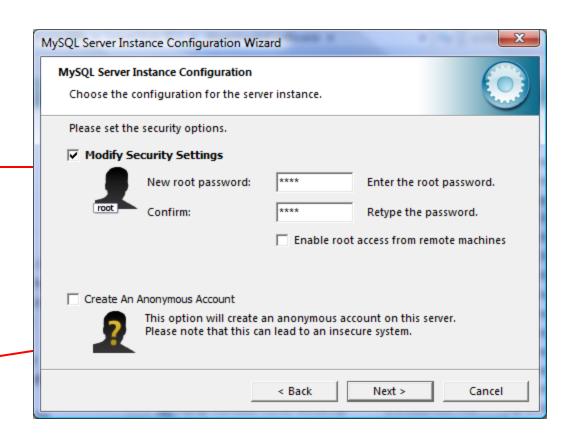

Accept default setting and enter a password for the root (superuser with all privileges by default). Enabling root access from remote machines is only necessary if you will be accessing the DB as the root user from a remote machine – we will not be doing this in this course.

Do not enable this option

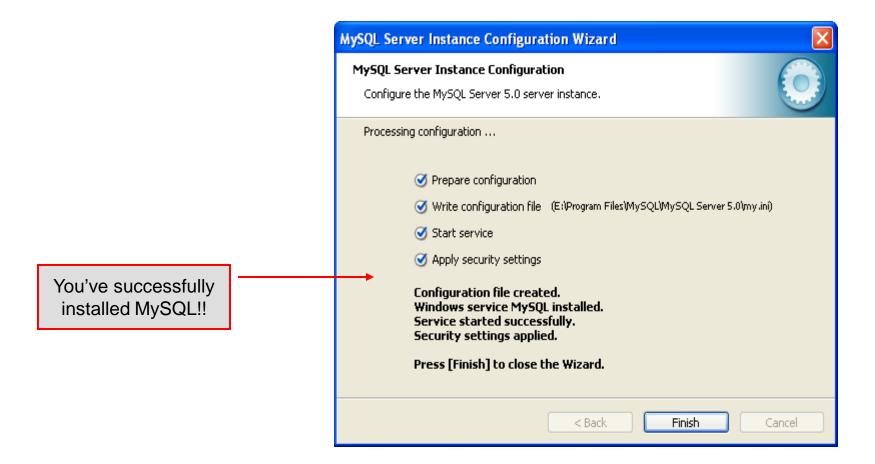

MySQL Server Instance Configuration Wizard MySQL Server Instance Configuration Configure the MySQL Server 5.1 server instance. Ready to execute ... Prepare configuration Write configuration file Start service Apply security settings Please press [Execute] to start the configuration. Execute < Back Cancel

Configuration is about to begin. Now cross your fingers, toes, and anything else you have, take a deep breath, click the Execute button and close your eyes for a few seconds.

When they all have green check marks in them – you're good to go!

# Running MySQL 5.5.20

- If you've successfully installed MySQL, it should now be running as a service on your machine. It will start automatically when your machine boots.
- Go into your listing of programs (from the start menu at the bottom: All Programs) and you should see MySQL appear. Since you will be running MySQL clients a lot, it will be easier if you pin the MySQL Client to the start menu.
- To verify that MySQL is running properly as a service you can either check the process window or run a MySQL client.

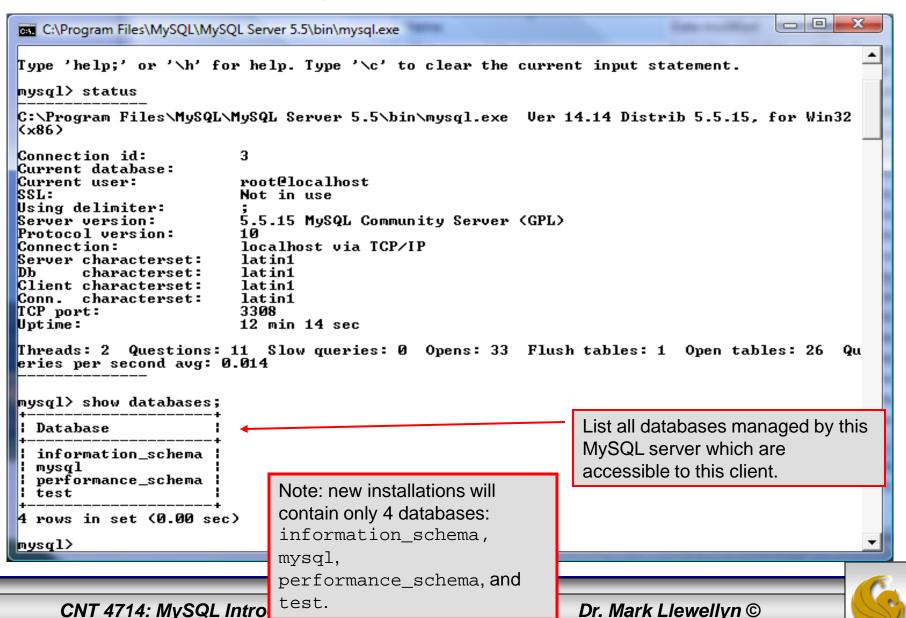

# Running MySQL 5.5.20 (cont.)

#### Specifying A Database Within MySQL

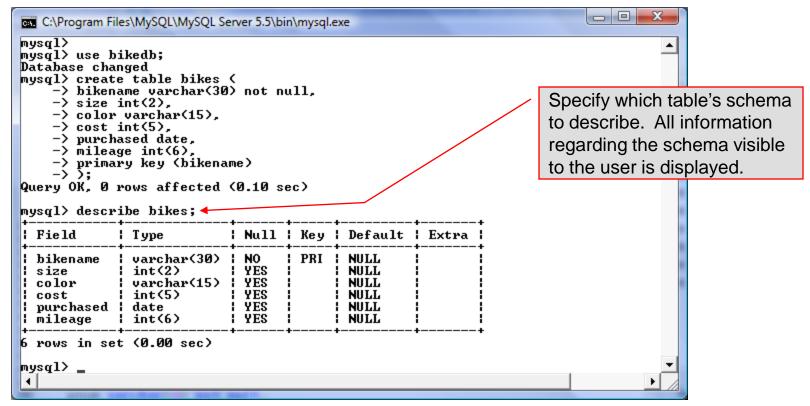

- Unless, it is specifically stated, in the following slides we'll assume that the user has root-level privileges.
- To select a database for use in MySQL the use command must be issued. In the example below, we'll select the bikedb database.

#### Viewing the Schema of a Relation

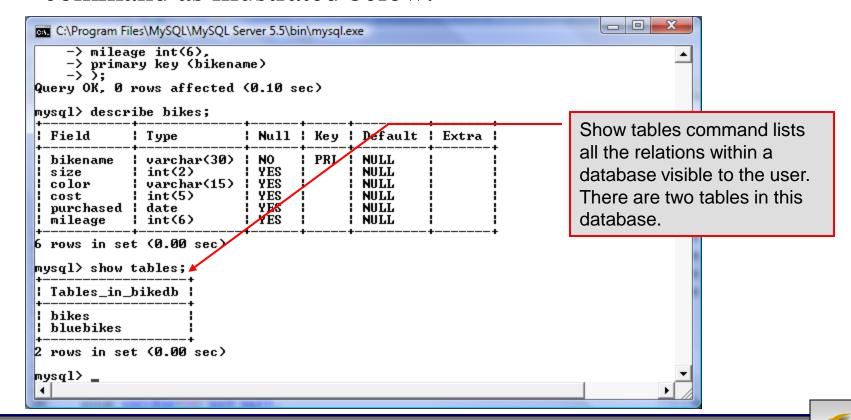

• To see the schema of a relation within a database, use the describe <tablename> command as illustrated below.

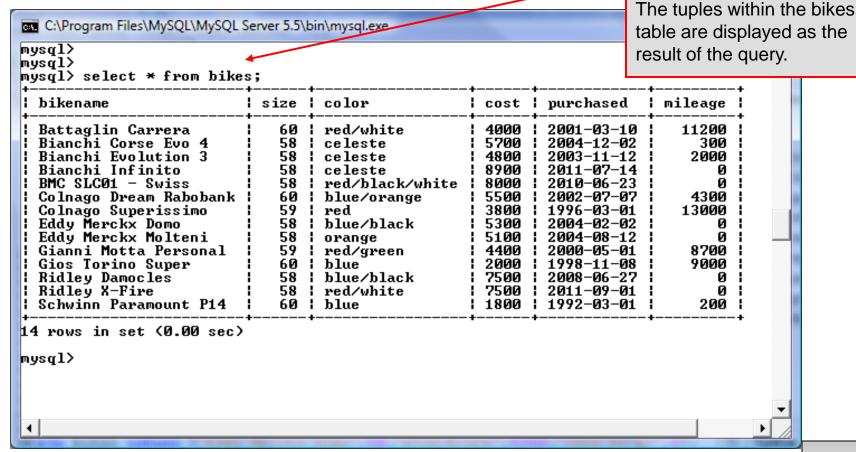

#### Viewing the Relations of a Database

• Once a database has been selected you can see the relations (tables) within that database with the show tables command as illustrated below.

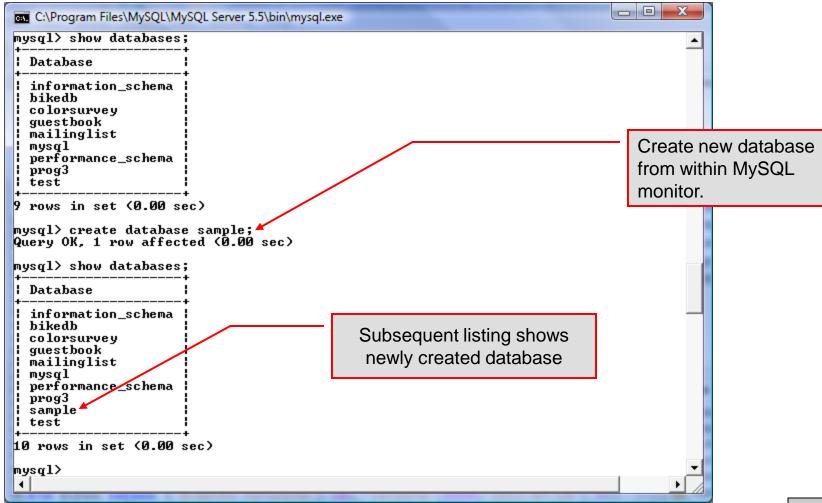

#### Running a Simple Select Query in MySQL

• Within the MySQL monitor, running an SQL query is straight forward. The example below illustrates a simple selection query on the bikes table of the biked database.

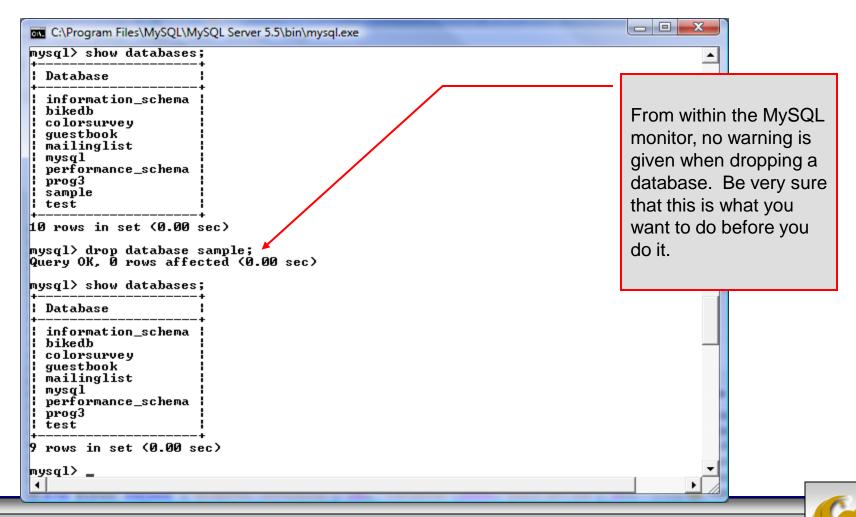

## Creating a Database in MySQL

From the MySQL monitor enter create database <db name>

## Dropping a Database in MySQL

 From the MySQL monitor execute the drop database <db name > command.

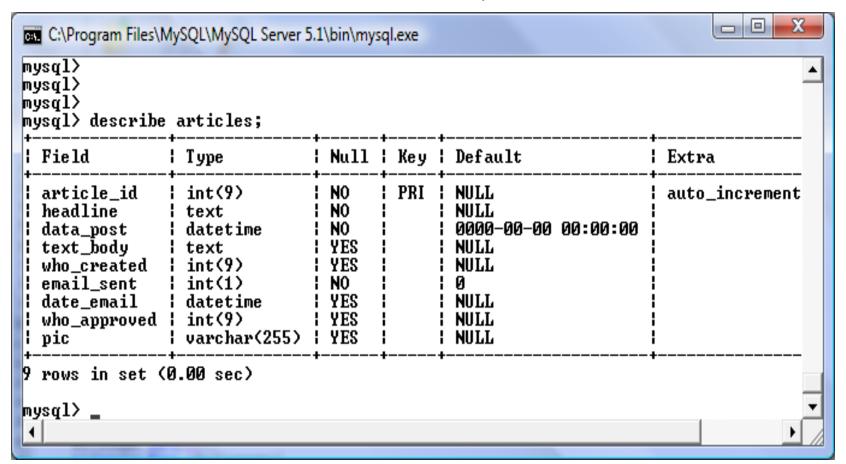

## Manipulating Tables in MySQL

- The creation of a database does not place any relations into the database. Relations must be separately created.
- To create a table within a database, first select the database (or create one if you haven't already done so), then execute the create table command.

```
C:\Program Files\MySQL\MySQL Server 5.1\bin\mysql.exe
mysql> use sample;
Database changed
mysql> create table articles (
    -> article_id int(9) not null auto_increment,
    -> headline text not null,
    -> data_post datetime not null default '0000-00-00 00:00:00',
    -> text_body text,
    -> who_created int(9) default null,
    -> email_sent int(1) not null default '0',
    -> date_email datetime default null,
    -> who_approved int(9) default null,
    -> pic varchar(255) default null,
    -> primary key (article_id)
Query OK, 0 rows affected (0.04 sec)
mysql>
```

Screen shot that describes the newly created table.

• The create table command has the following general format:

```
create [temporary] table
[if not exists] tablename
[(create_definition, ...)]
[table_options] [select_statement];
```

• If the [if not exists] clause is present, MySQL will produce an error message if a table with the specified name already exists in the database, otherwise the table is created.

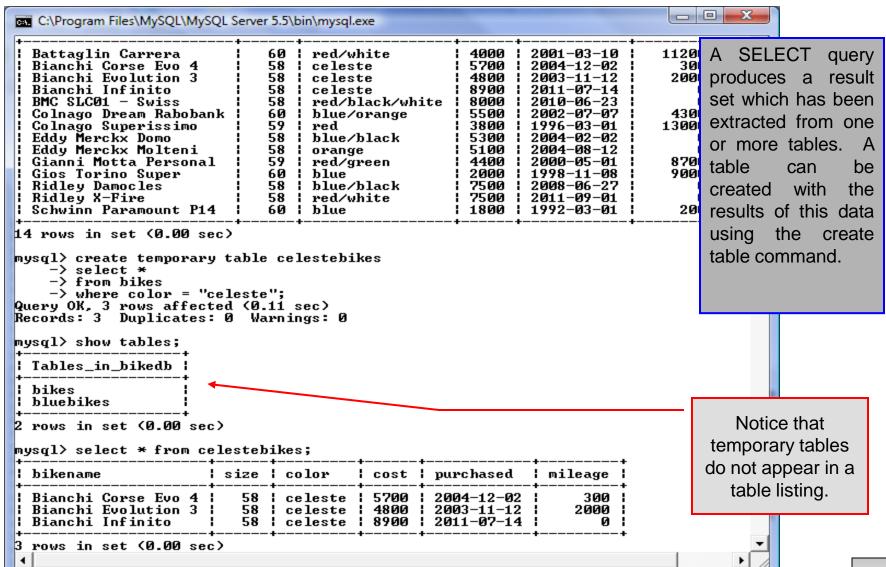

- A temporary table exists only for the life of the current database connection. It is automatically destroyed when the connection is closed or dies.
- Two different connections can use the same name for a temporary table without conflicting with one another.
- Temporary tables are most useful when queries get complex and intermediate results become useful. Also, versions of MySQL earlier than version 4.1 do not have subselect capability and temporary tables are a convenient way to simulate subselect query results.

Note: Non-root users require special permission to be able to create temporary tables. These users must have the Create\_tmp\_tables privilege set in the user grant table. We'll see more on this later.

#### Creating A Temporary Table From A Select Query

 Recall that the create table command has the following general format:

```
create [temporary] table
[if not exists] tablename
[(create_definition, ...)]
[table_options]
[select_statement];
```

• The table options allow you to specify the MySQL table type. The table type can be anyone of the six types listed in the table on the next slide.

Table Type	Description
ISAM	MySQL's original table handler
НЕАР	The data for this table is only stored in memory
MyISAM	A binary portable table handler that has replaced ISAM
MERGE	A collection of MyISAM tables used as one table
BDB	Transaction-safe tables with page locking
InnoDB	Transaction-safe tables with row locking

MySQL Table Types

ISAM, HEAP, and MyISAM are available for MySQL versions 3.23.6 or later.

MERGE, BDB, and InnoDB are available for MySQL versions 4.0 and later.

Default table type is InnoDB for MySQL versions 5.5.20.x.

## Altering A Table

• After a table has been created, it is possible to change the specifications of its schema. This is done through the alter table command:

alter table table\_name action\_list

- Note: Changing the schema of a table in a database is not something that is done very often once the database has been created. The time for altering the schema is during the design phase. Altering the schema of an operational database is a very dangerous thing.
- Multiple changes to the table can be made at the same time by separating actions with commas in the action\_list.
- The possible attribute (column) actions that can be used are shown in the table on the following slide.

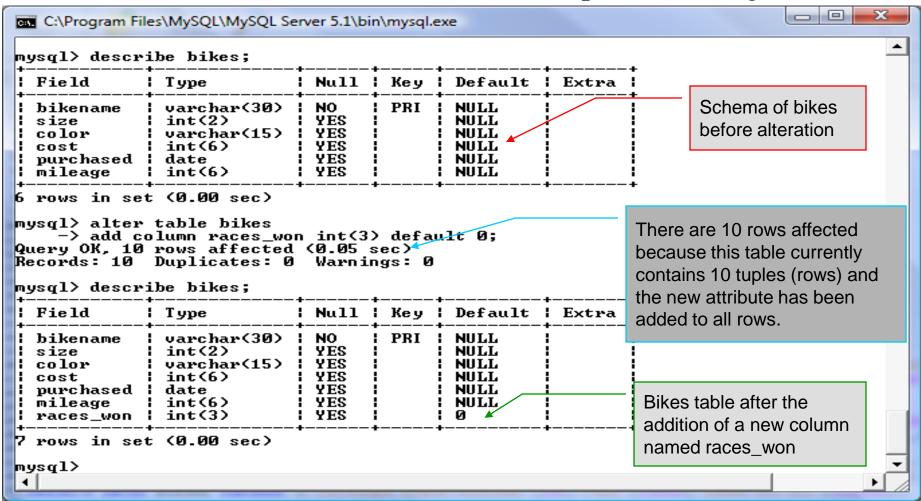

Action Syntax	Action Performed
add [column] column_declaration	Add a column to the table
[first   after column_name] alter [column] column name	Specify new default value for a
{set default literal   drop default}	column or remove old default
change [column] column_name	Modify column declaration with
column_declaration	renaming of column
modify [column] column_declaration	Modify column declaration without renaming column
drop [column] column_name	Drop a column and all data contained within it.
rename [as] new_table_name	Rename a table
table_options	Change the table options

Actions performed by alter table (column related) command

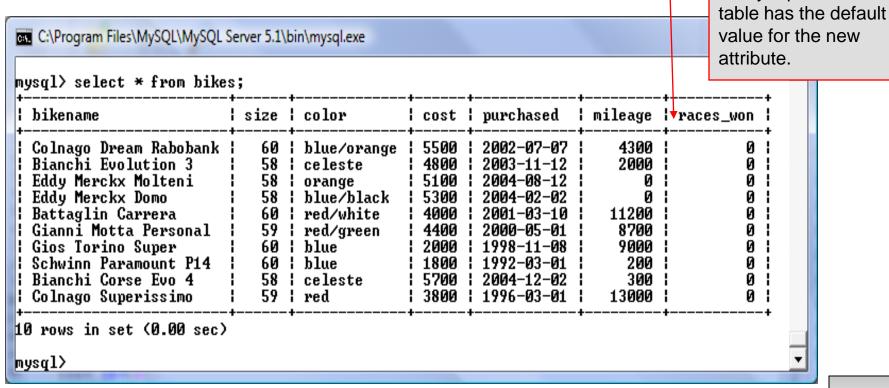

column\_name represents the current name of the column, column\_declaration represents the new declaration, in the same format as if it were in a create command.

• The screen shot below shows an example of altering a table.

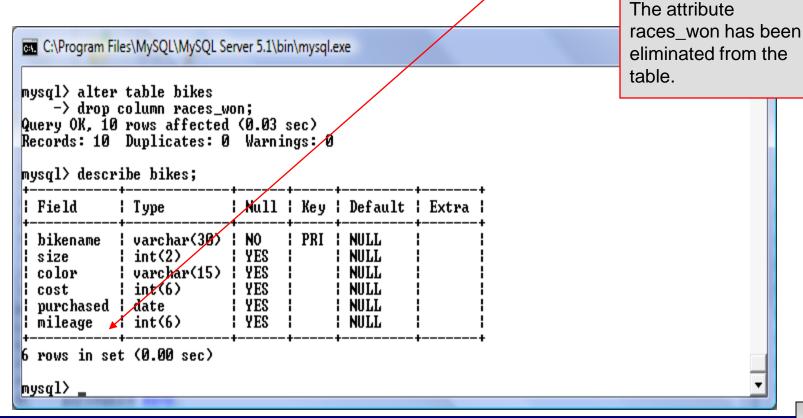

• The screen shot below shows the tuples currently in the bikes table after the addition of the new attribute illustrating that all of the tuples have assumed the default value on the new attribute.

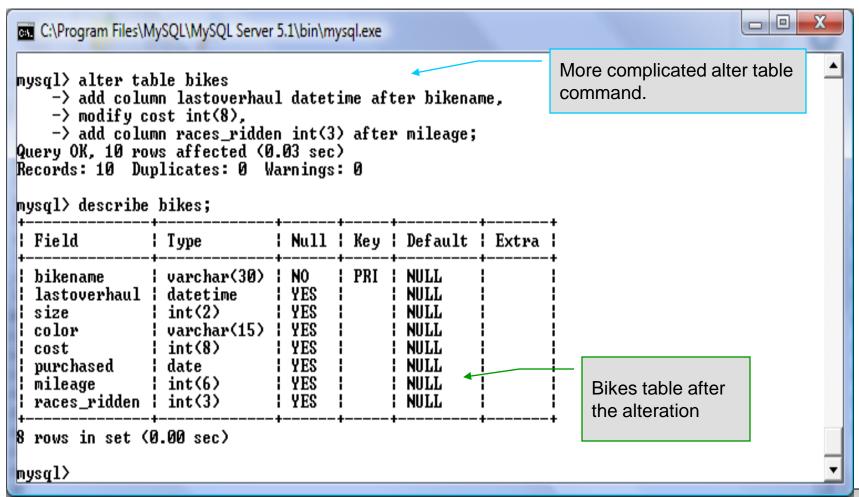

• The screen shot below illustrates dropping a column from a table.

Note that in general, this type of operation may not always be

allowed due to constraint violations.

• The screen shot below shows a more complicated example of altering a table.

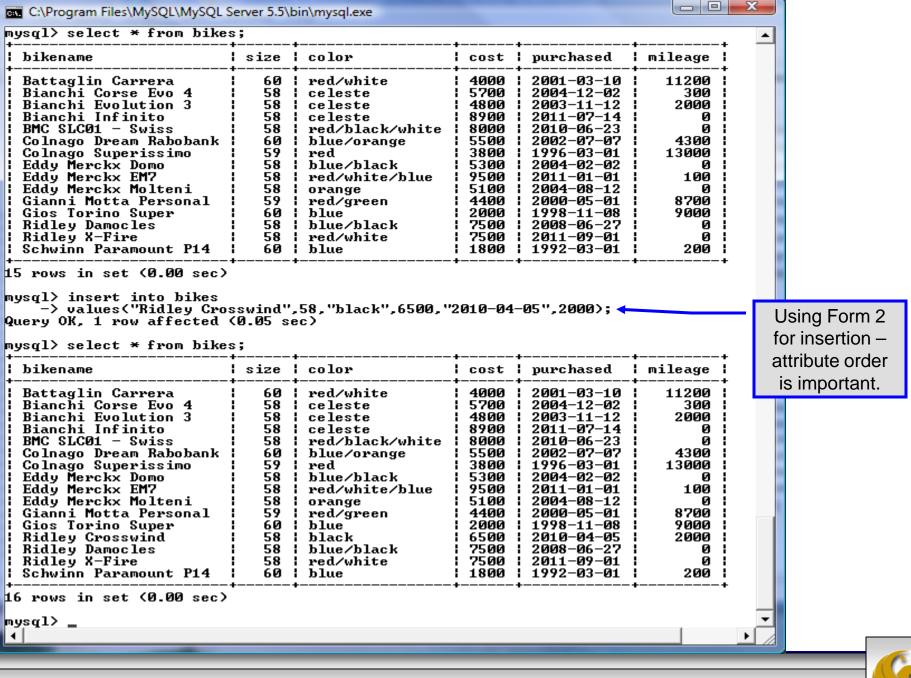

## Inserting Data Into A Table

- Data can be entered into a MySQL table using either the insert or replace commands.
- The insert statement is the primary way of getting data into the database and has the following form:

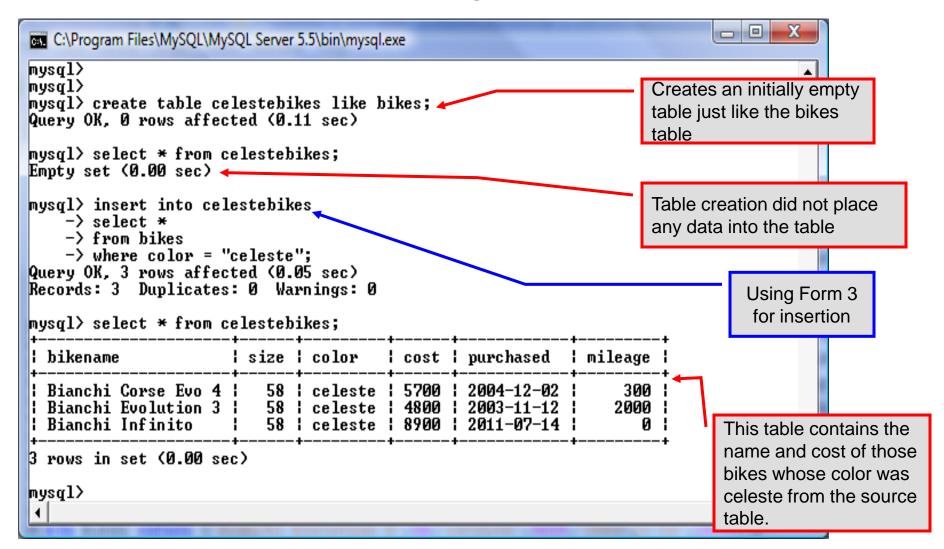

## Inserting Data Into A Table (cont.)

- Form 1 of the insert statement is the most verbose, but also the most common. The set clause explicitly names each column and states what value (evaluated from each expression) should be put into the table.
- Form 2 (insert values) requires just a comma separated list of the data. For each row inserted, each data value must correspond with a column. In other words, the number of values listed must match the number of columns and the order of the value list must be the same as the columns. (In form 1, the order is not critical since each column is named.)
- Form 3 is used to insert data into a table which is the result set of a select statement. This is similar to the temporary table example seen earlier in the notes.
- The following couple of pages give some examples of the different forms of the insert command.

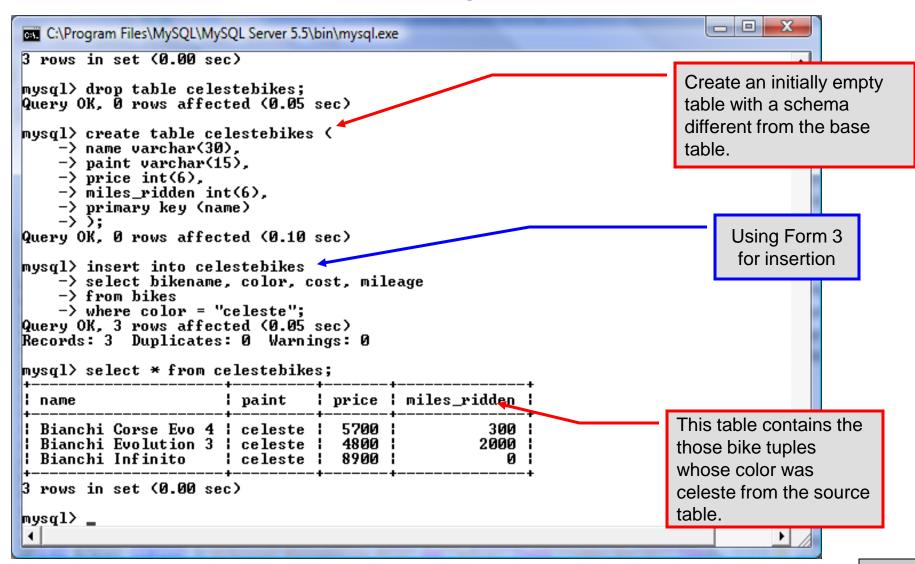

#### Examples: Inserting Data Into A Table

#### Examples: Inserting Data Into A Table

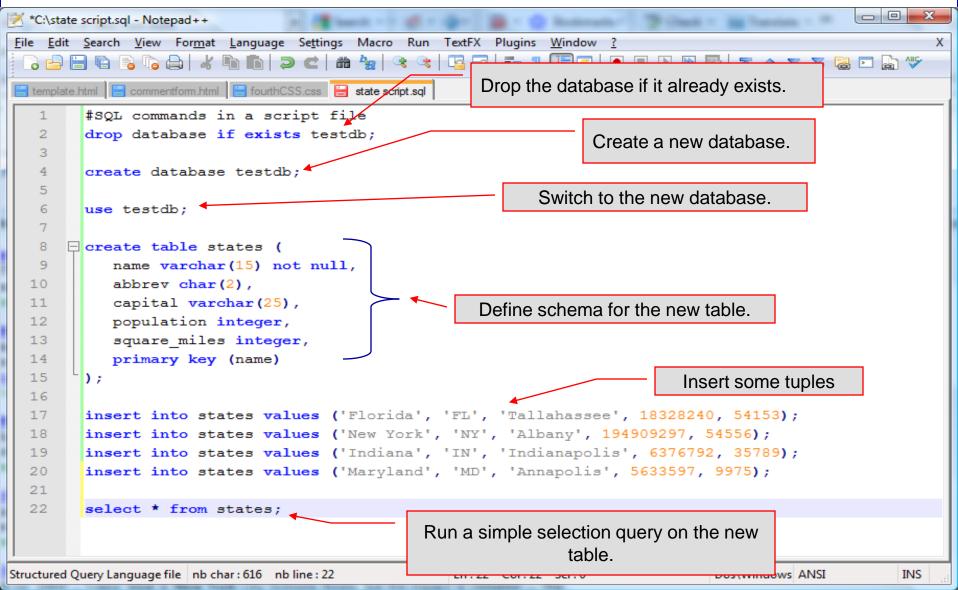

## Using Scripts with MySQL

- Entering data to create sample databases using conventional SQL commands is tedious and prone to errors. A much simpler technique is to use scripts. The following illustrates two techniques for invoking scripts in MySQL.
- Create your script file using the text editor of your choice.
- Comments in the SQL script files begin with a # symbol.
- In the script file example shown on the next slide, I drop the database in the first SQL command. Without the if exists clause, this will generate an error if the database does not exist. The first time the script executes (or subsequent executions if the database is dropped independently) the error will be generated...simply ignore the error.

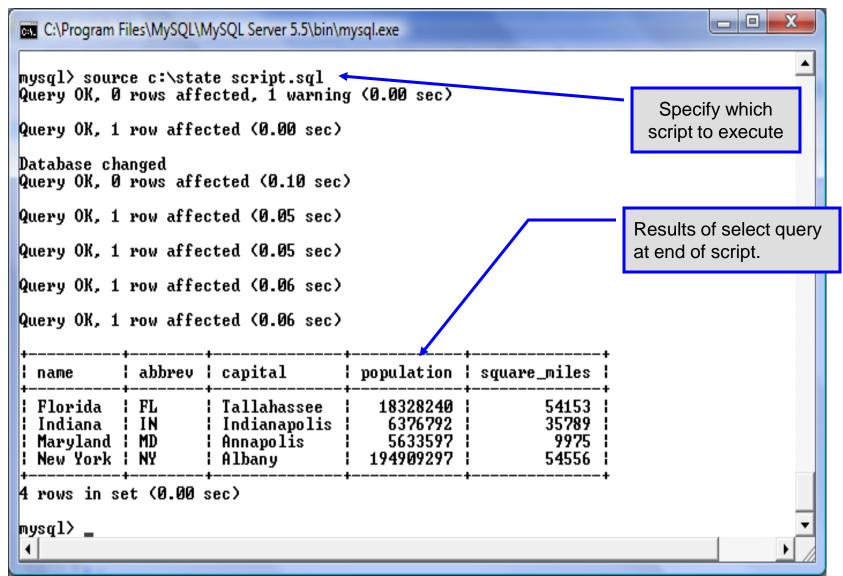

## Using Scripts with MySQL (cont.)

## Using Scripts with MySQL (cont.)

#### Importing Data Using the mysqlimport Utility

- As with many things in MySQL there are several ways to accomplish a specific task. For getting data into tables, the mysqlimport utility is also useful.
- The mysqlimport utility reads a range of data formats, including comma- and tab- delimited, and inserts the data into a specified database table. The syntax for mysqlimport is:

```
mysqlimport [options] database_name file1 file2 ...
```

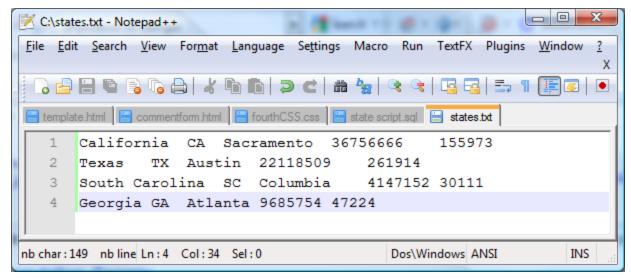

- This utility is designed to be invoked from the command line.
- The name of the file (excluding the extension) must match the name of the database table into which the data import will occur. Failure to match names will result in an error.

## Importing Data Using the mysqlimportUtility (cont.)

• The file shown below was created to import additional data into the states table within the testdb database used in the previous

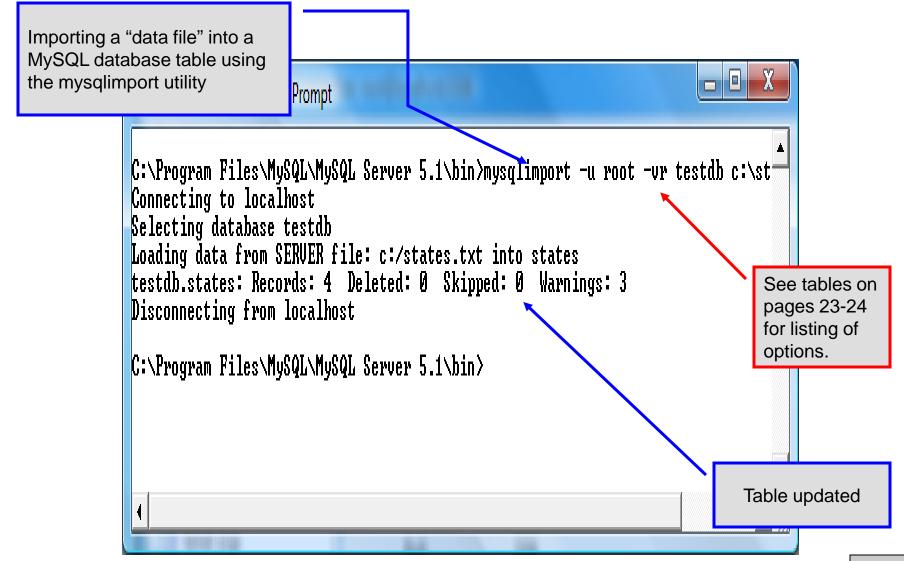

example.

• In this case, the default field delimiter (tab), default field enclosure (nothing), and the default line delimiter (\n) were used. Many options are available and are illustrated in the table on pages 65-66.

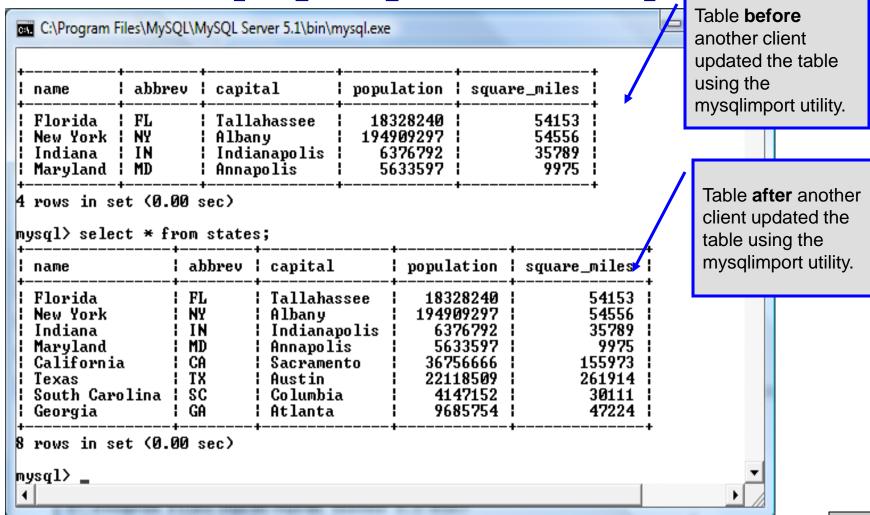

## Importing Data Using the mysqlimportUtility

## Importing Data Using the

mysqlimportUtility

## mysqlimportUtility Options

Option	Action
-r or -replace	Causes imported rows to overwrite existing rows if they have the same unique key value.
-i or –ignore	Ignores rows that have the same unique key value as existing rows.
-f or -force	Forces mysqlimport to continue inserting data even if errors are encountered.
-l or –lock	Lock each table before importing (a good idea in general and especially on a busy server).
-d or –delete	Empty the table before inserting data.
fields-terminated-by='char'	Specify the separator used between values of the same row, default \t (tab).
fields-enclosed-by='char'	Specify the delimiter that encloses each field, default is none.

## mysqlimport Utility Options (cont.)

Option	Action
fields-optionally-enclosed- by='char'	Same as –fields-enclosed-by, but delimiter is used only to enclosed string-type columns, default is none.
fields-escaped-by='char'	Specify the escape character placed before special characters; default is \.
lines-terminated-by='char'	Specify the separator used to terminate each row of data, default is \n (newline).
-u or -user	Specify your username
-p or –password	Specify your password
-h or -host	Import into MySQL on the named host; default is localhost.
-s or -silent	Silent mode, output appears only when errors occur.
-v or -verbose	Verbose mode, print more commentary on action.
-? or –help	Print help message and exit

## Importing Data From A File With SQL Statement Load Data Infile

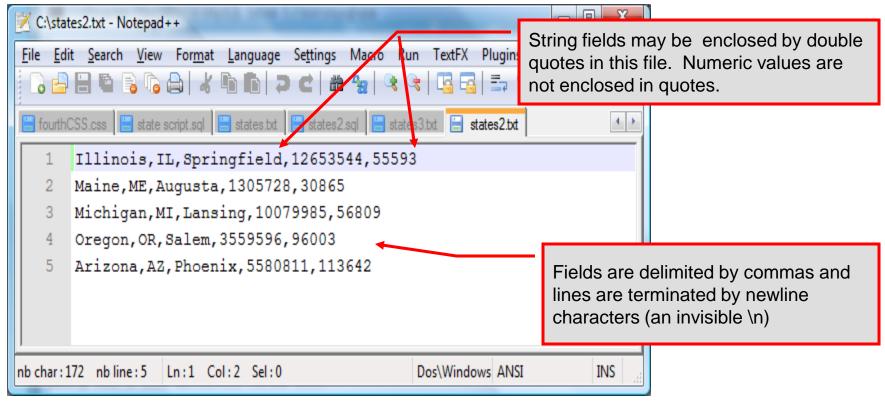

- Using the utility mysqlimport to load data into a table from an external file works well if the user has access to a command window or command line.
- If you have access via a connection to only the MySQL database, or you are importing data from within an executing application, you will need to use the SQL statement Load Data Infile.
- The Load Data Infile statement also provides a bit more flexibility since the file name does not need to match the table name. Other than that the options are basically the same and the same results are accomplished.
- The example on page 70 illustrates this SQL command which is available in MySQL.

# Importing Data From A File With SQL Statement Load Data Infile (cont.)

The basic form of the Load Data Infile statement is:

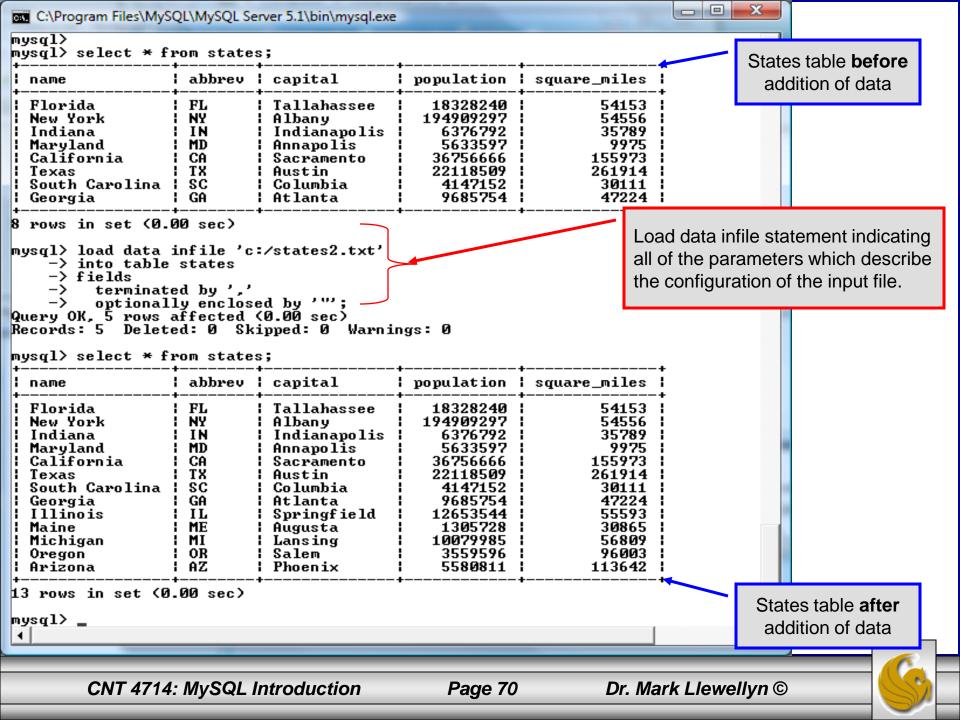

```
LOAD DATA [LOW PRIORITY
                                  CONCURRENT | [LOCAL | INFILE 'filename'
                                   Either allow concurrent update or block until no other clients
              IGNORE]
[REPLACE
                                   are reading from the specified table. See page 75.
INTO TABLE tablename
                                                      Same as -r and -i options in
[FIELDS
                                                      mysglimport utility - either replace
                                                      or ignore rows with duplicate keys.
      [TERMINATED BY 'char']
                                                                  Sets the characters
        [OPTIONALLY] ENCLOSED BY 'char']
                                                                  that delimit and
                                                                  enclose the fields
      [ESCAPED BY '\char'] ]
                                                                  and lines in the data
[LINES
                                                                  file. Similar to
                                                                  mysglimport syntax.
      [STARTING BY 'char']
      [TERMINATED BY 'char']
[IGNORE number LINES] -
                                      Ignores lines at the start of the file (miss header info)
[(column_name, ...)]
                                         Used to load only certain columns (not entire rows)
```

## Load Data Infile Example

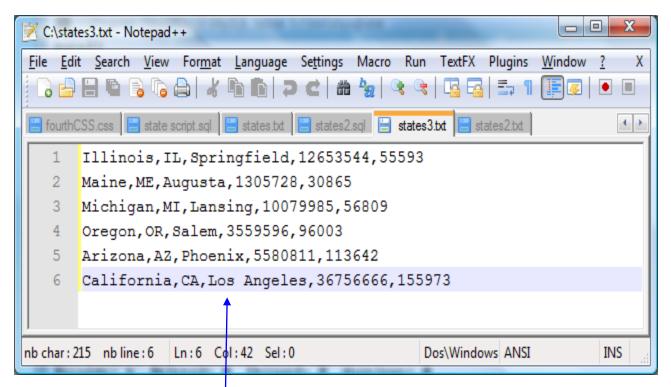

Text file containing the data to be loaded into the database table.

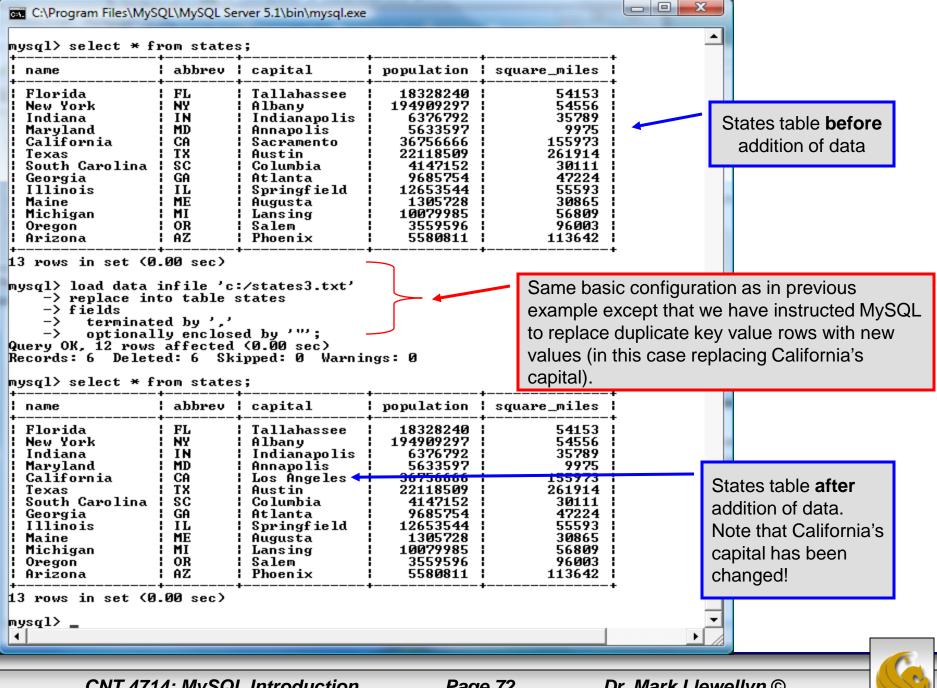

## Load Data Infile Example 2

Text file containing the data to be loaded into the database table.

California already exists in the states table – this one will replace the value of the capital with a different value.

## The Ignore Clause of the Insert Command

- While the normal issues of data type compatibility are always of concern, there are other issues to deal with when inserting data into tables.
- There is the possibility that a duplicate of a key may be entered. If so, you will see an error like this:

```
ERROR 1062: Duplicate entry '2' for key 1
```

- It is possible to subdue errors by using the keyword ignore in the insert statement. By using ignore any duplicate rows will simply be ignored. They won't be imported, and the data at the related row of the target table will be left untouched.
  - In your application, you would be wise to check how many rows were affected (imported) whenever using ignore because ignoring a record may constitute a failure condition in your application that needs to be handled.

## Low Priority and Delayed Inserts

- If you specify insert low-priority, the insert waits until all other clients have finished reading from the table before the insert is executed.
- If you specify insert delayed, the client performing the action gets and instant acknowledgement that the insert has been performed, although in fact the data will only be inserted when the table is not in use by another thread.
  - This may be useful if you have an application that needs to complete its process in minimum time, or simply where there is no need for it to wait for the effect of an insert to take place. For example, when you're adding data to a log or audit trail.
  - This feature applies only to ISAM or MyISAM type files.

## Inserting/Replacing Data Using Replace

- Data can also be entered into a MySQL table using the replace command.
- The replace statement has forms similar to the insert statement:

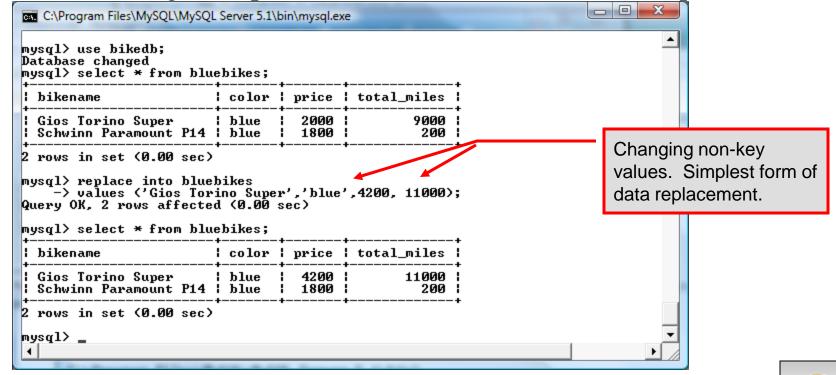

```
replace [low priority | delayed] [ignore] [into]table_name [(column_name,...)] select...
```

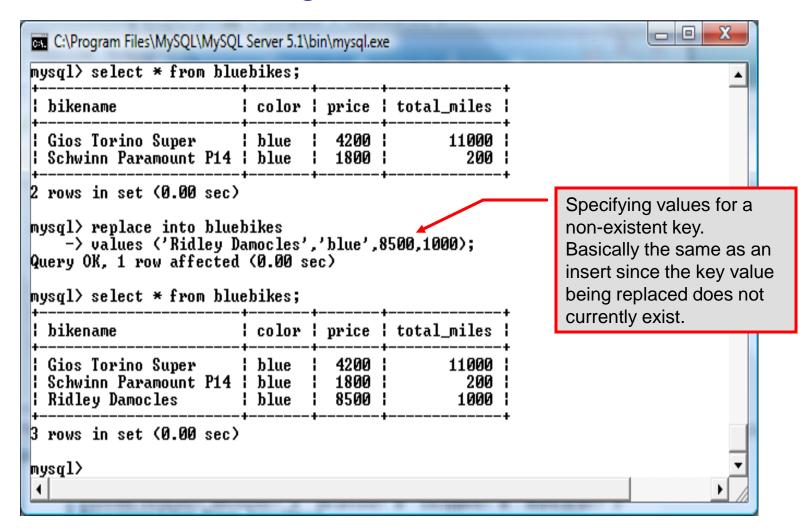

## Using replace

• The replace statement works similar to insert. It always tries to insert the new data, but when it tries to insert a new row with the same primary or unique key as an existing row, it deletes the old row and replaces it with the new values.

The following examples will illustrate how replace operates.

### Using Replace (cont.)

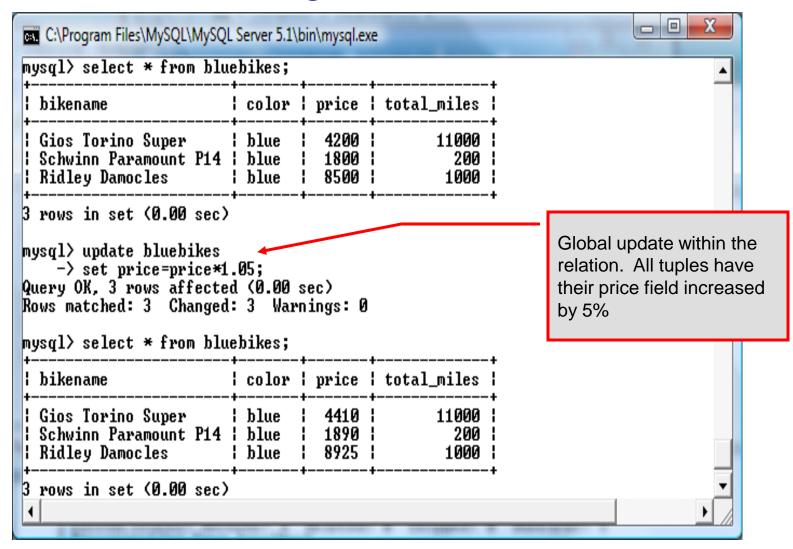

## Performing Updates on Tables

• The update command allows you to modify the values of the existing data in a table. The basic format of the statement is:

- There are basically two parts to the statement: the set portion to declare which column to set to what value; and the where portion, which defines which rows are to be affected.
- Limit restricts the number of rows affected to num.

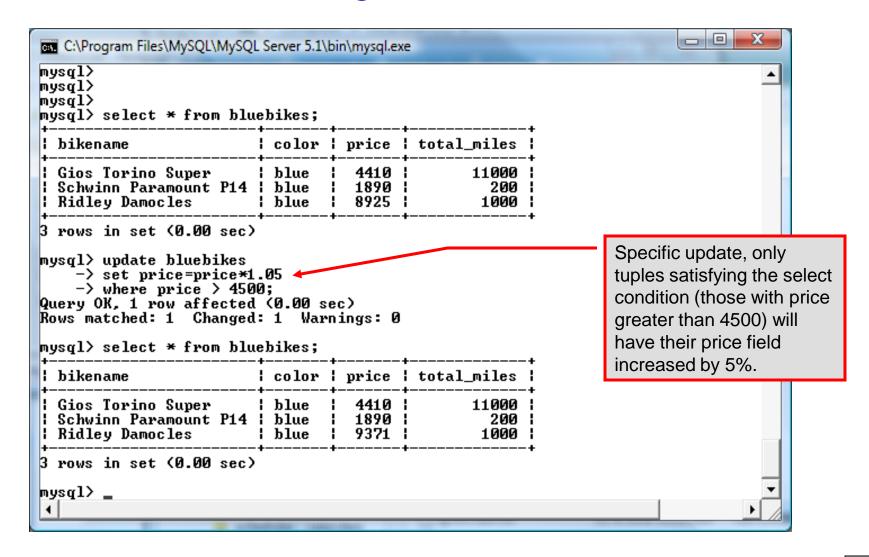

#### Using update (cont.)

#### Using update (cont.)

# Select Queries in MySQL

• The select command in MySQL is basically the same as in the standard SQL, however, it does have some additional features. The basic format of the statement is (not all options are shown – for complete details see the SQL Manual):

```
SELECT [ALL | DISTINCT | DISTINCTROW][HIGH_PRIORITY]
       [STRAIGHT JOIN] [SQL_SMALL_RESULT][SQL_BIG_RESULT]
       [SQL_BUFFER_RESULT][SQ_CACHE | SQL_NO_CACHE]
       select_expression, ...
   [INTO {OUTFILE | DUMPFILE} 'path/to/filename' export_options]
   [FROM table references
        WHERE where definition]
         [GROUP BY {col_name | col_alias | col_pos | formula}
                 [asc |desc], ...]
         [HAVING where_definition]
         [ORDER BY {col_name | col_alias | col_pos | formula}
                 [asc | desc], ...]
         [LIMIT [offset, ] num rows]
         [PROCEDURE procedure name];
```

## MySQL RDBMS (cont.)

- MySQL features a user permissions system, which allows control over user's access to the databases under MySQL control.
- There are very few competitors of MySQL (Oracle, Sybase, DB2, and SQL Server) that can match the level of sophistication provided by MySQL's permissions system in terms of granularity and level of security provided.

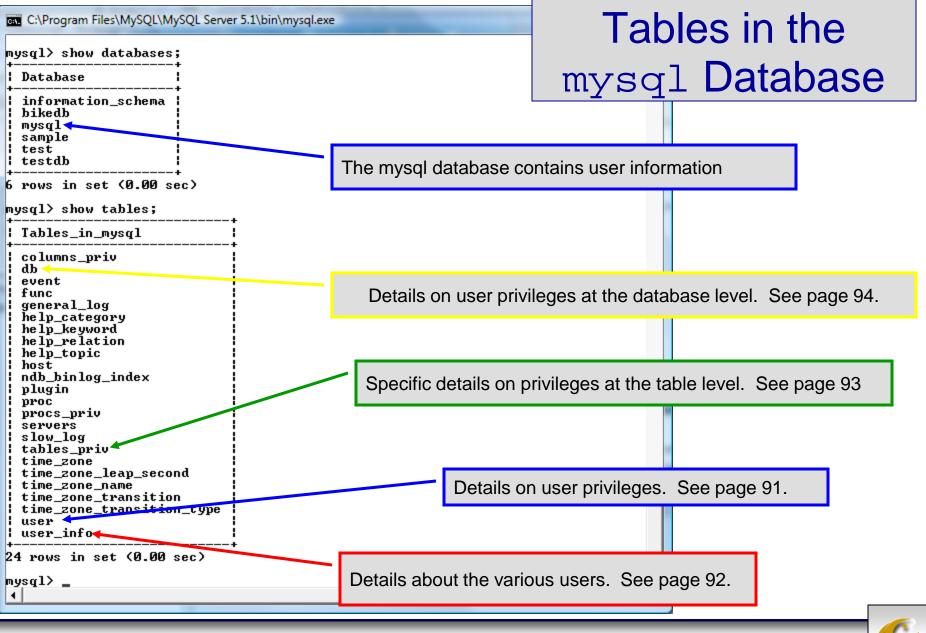

Note that I did not include Microsoft Access in the list above. There are a couple of reasons for this; Access concentrates on the client front-end, although available in shareable versions, it lacks the management system that is a key part of any RDBMS. Access provides virtually no user authentication capabilities nor does it have multithreading processing capabilities, in its normal form.

## Authorization in MySQL

- mysql and the various utility programs such as mysqladmin, mysqlshow, and mysqlimport can only be invoked by a valid MySQL user.
- Permissions for various users are recorded in grant tables maintained by MySQL.
- As the root user, you have access to all the databases and tables maintained by the MySQL Server.
- One of these databases is named mysql.and contains the various information on the users who have access to this installation of MySQL. Some of the tables which comprise this database are shown on the next few pages.

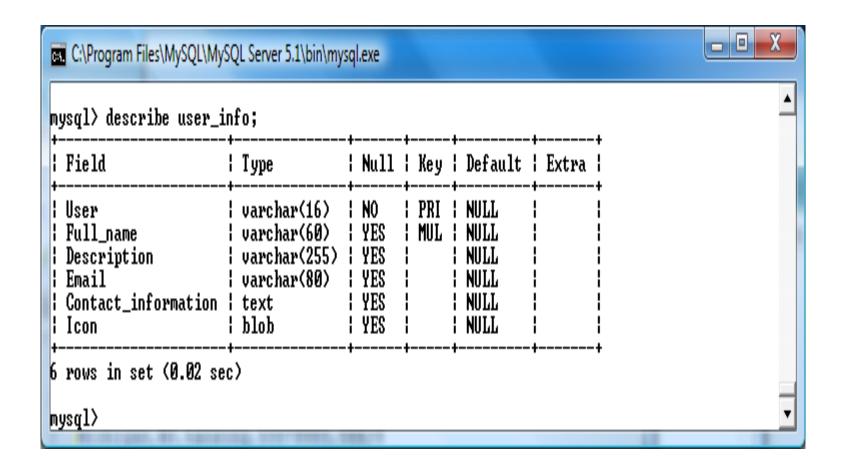

#### Contents of the user Table

#### **How The Grant Tables Work**

- The various grant tables work together to define access capabilities for the various users of the databases in MySQL. The tables represent a hierarchy which begins at the database level and moves downward to finer and finer granularity in access capabilities.
- To understand how the grant tables work, it is necessary to understand the process that MySQL goes through when considering a request from a client.
- Step 1: A user attempts to connect to the MySQL server. The user table is consulted, and on the basis of the username, password, and host from which the connection is occurring, the connection is either refused or accepted. (MySQL actually sorts the user table and looks for the first match.)

#### How The Grant Tables Work (cont.)

- Step 2: If the connection is accepted, any privilege fields in the user table that are set to 'Y' will allow the user to perform that action on any database under the server's control. For administrative actions such as shutdown and reload, the entry in the user table is deemed absolute, and no further grant tables are consulted.
- Step 3: Where the user makes a database-related request and the user table does not allow the user to perform that operations (the privilege is set to 'N'), MySQL consults the db table (see page 84).
- Step 4: The db table is consulted to see if there is an entry for the user, database, and host. If there is a match, the db privilege fields determine whether the user can perform the request.

#### How The Grant Tables Work (cont.)

Step 5: If there is a match on the db table's Db and User files but Host is blank, the host table is consulted to see whether there is a match on all three fields. If there is, the privilege fields in the host table will determine whether the use can perform the requested operation. Corresponding entries in the db and host tables must both be 'Y' for the request to be granted. Thus, an 'N' in either table will block the request.

Step 6: If the user's request is not granted, MySQL checks the tables\_priv (see page 83) and columns\_priv tables. It looks for a match on the user, host, database, and table to which the request is made (and the column, if there is an entry in the columns\_priv table). It adds any privileges it finds in these tables to the privileges already granted. The sum of these privileges determines if the request can be granted.

#### Managing User Privileges with GRANT and REVOKE

- The basic granting and revocation of privileges in MySQL are accomplished through the grant and revoke commands.
- The format of the grant command is:

```
GRANT privileges [(column_list)]
ON
    database name.table name
TO username@hostname [IDENTIFIED BY 'password']
 [REQUIRE [SSL |
                X509]
    [CIPHER cipher [AND] ]
    [ISSUER issuer [AND] ]
    [SUBJECT subject ] ]
 [WITH GRANT OPTION
    MAX_QUERIES_PER_HOUR
                           num
    MAX_UPDATES_PER_HOUR
                           num
    MAX CONNECTIONS PER HOUR
                               num
```

#### Some of the Privileges Assigned with GRANT

Privilege	Operations Permitted				
ALL or ALL PRIVILEGES	All privileges except for GRANT				
ALTER	Change a table definition using ALTER TABLE excluding the creation and dropping of indices.				
CREATE	Create database or tables within a database.				
CREATE TEMPORARY TABLES	Create temporary tables.				
DELETE	Ability to perform deletions from tables. (Delete DML statements).				
DROP	Ability to drop databases or tables.				
INSERT	Ability to insert data into tables.				
SHUTDOWN	Ability to shutdown the MySQL server.				

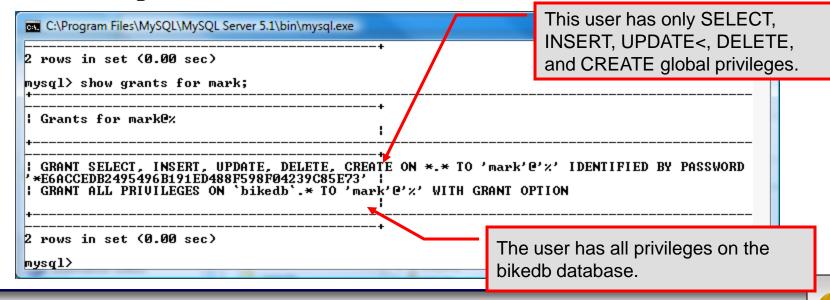

## Displaying Privileges with SHOW

- The SQL command SHOW is used to display the grant privileges for a given user.
- The syntax for the SHOW command is:

SHOW GRANTS FOR username@hostname

An example is shown below:

#### Revoking User Privileges with REVOKE

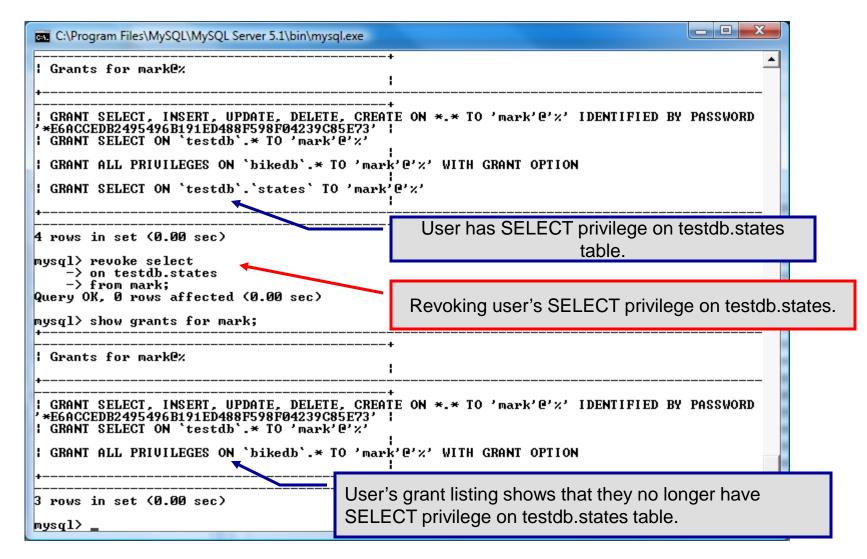

- Revocation of privileges in MySQL is accomplished with the revoke command.
- The format of the revoke command is:

```
REVOKE privileges [(column_list)]
ON database_name.table_name
FROM username@hostname
```

An example is shown on the next page.

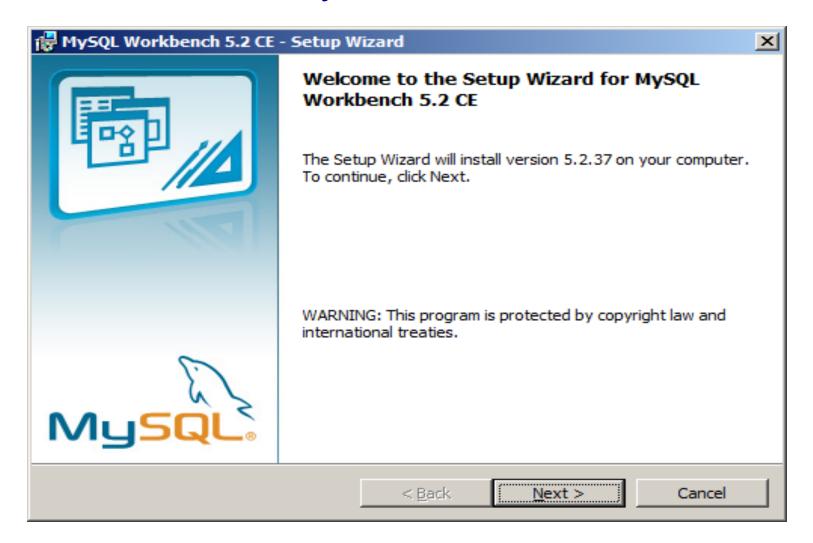

#### Example - Revoking User Privileges with REVOKE

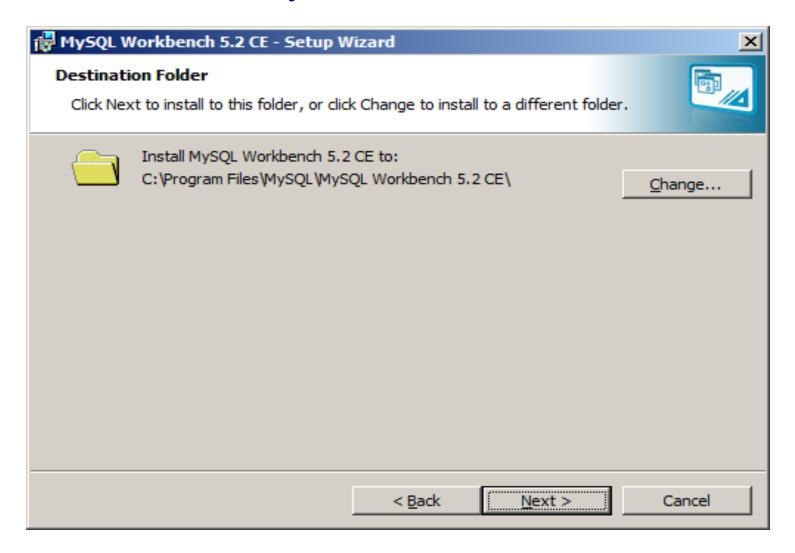

- From MySQL you can download a GUI-based tool that allows you to create, manipulate, and administer MySQL databases.
- The current version of this tool (5.2.37) does not implement full functionality of the GRANT command down to the attribute level.
- This tool also contains some system administrator functionality for monitoring system resources and utilization.
- You can download this tool at: <a href="http://www.mysql.com/products/">http://www.mysql.com/products/</a> (see page 7).
- The install/set-up for this tool as well as a few screen shots of this tool and its capabilities are shown in the next few slides.

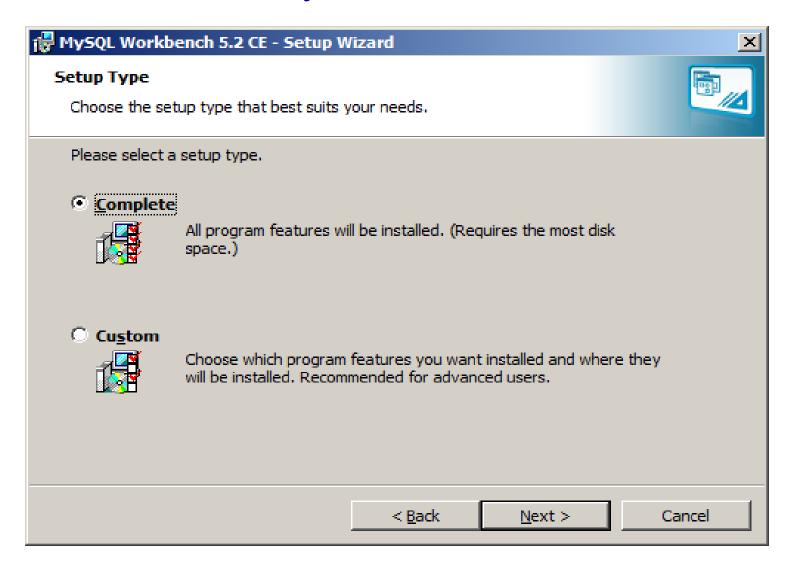

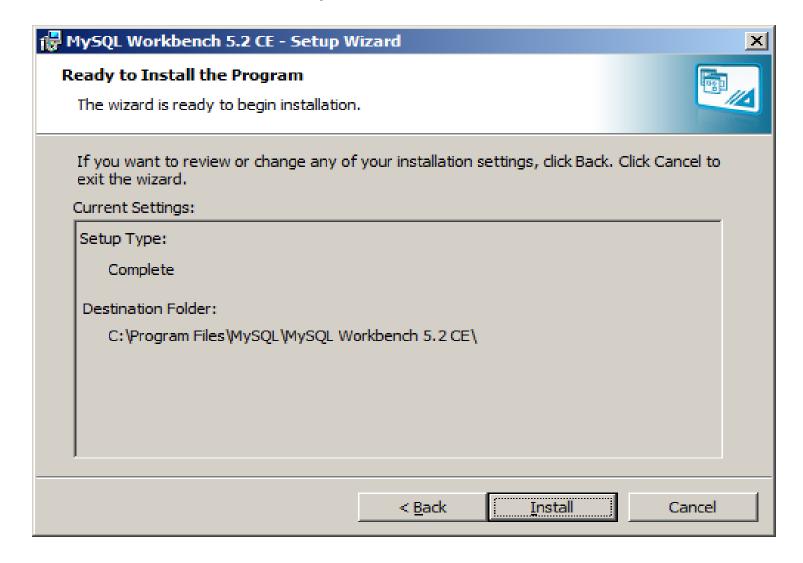

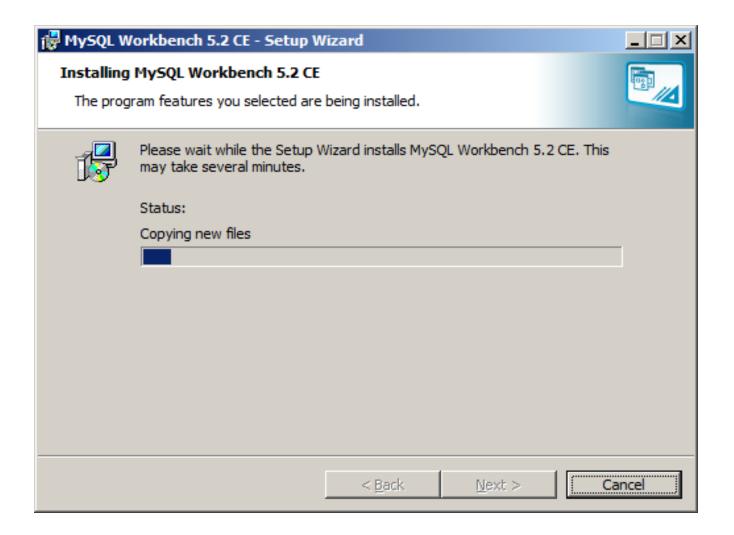

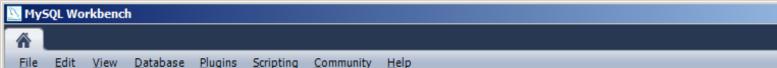

#### Workbench Central

#### Welcome to MySQL Workbench

What's New in This Release? Read about all changes in this MySQL Workbench release.

Workspace

#### SQL Development

#### Data Modeling

Create and manage models, forward & reverse engineer, compare and synchronize schemas, report.

#### Server Administration

Configure your database server, setup user accounts, browse status variables and server logs.

#### Open Connection to Start Querying

#### Open Existing EER Model

#### Server Administration

New Server Instance

Or click to manage a database server instance.

#### **New Connection**

Select a connection and schema table to edit.

#### Edit SQL Script

Ready.

#### Manage Connections

#### Create New EER Model

#### Create EER Model From Existing Database

#### Manage Import / Export

#### Manage Security

#### Manage Server Instances
