Department of Electrical Engineering and Computer Science Computer Science Division University of Central Florida

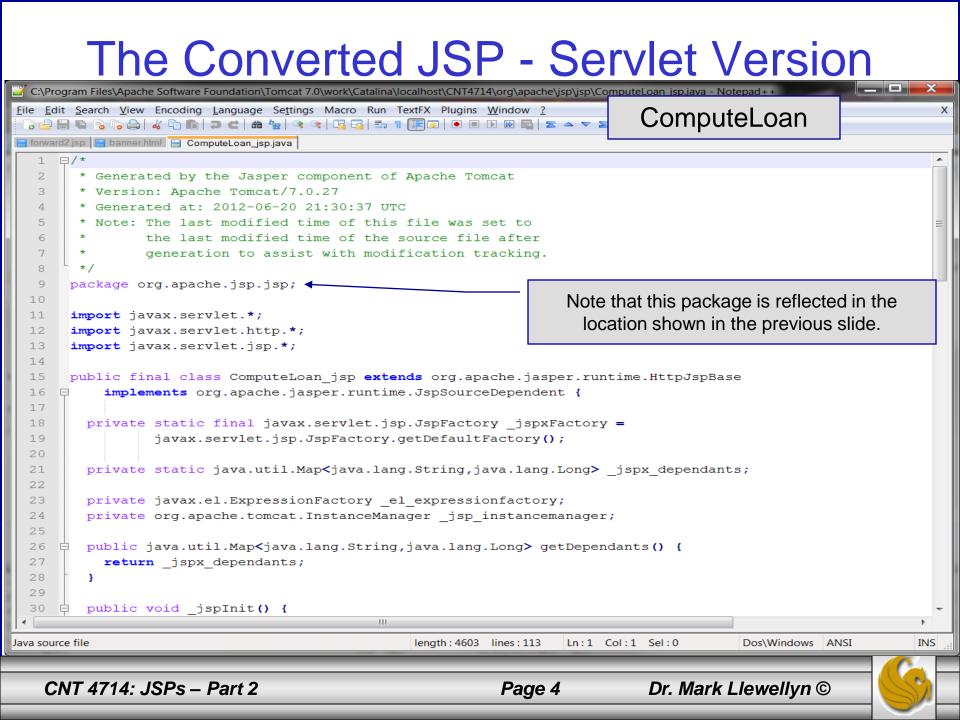

A JSPs Conversion To A Servlet

- As shown in the diagram of the lifecycle of a JSP shown in part 2 (page 2), a JSP is converted into a servlet during execution.
- While the converted servlet looks very similar in nature to those we have already seen, there are some differences.
- Within Tomcat, the servlet version of the JSP is stored in the work directory (see part 2, page 12).
- The exact directory within the work directory depends in part on your Tomcat set-up and in part on your web-application structure. The next slide illustrates the location of the servlet files that were generated for the ComputeLoan.jsp and ComputeLoan2.jsp applications that appeared in part 2 of the notes on pages 7 and 13 respectively.

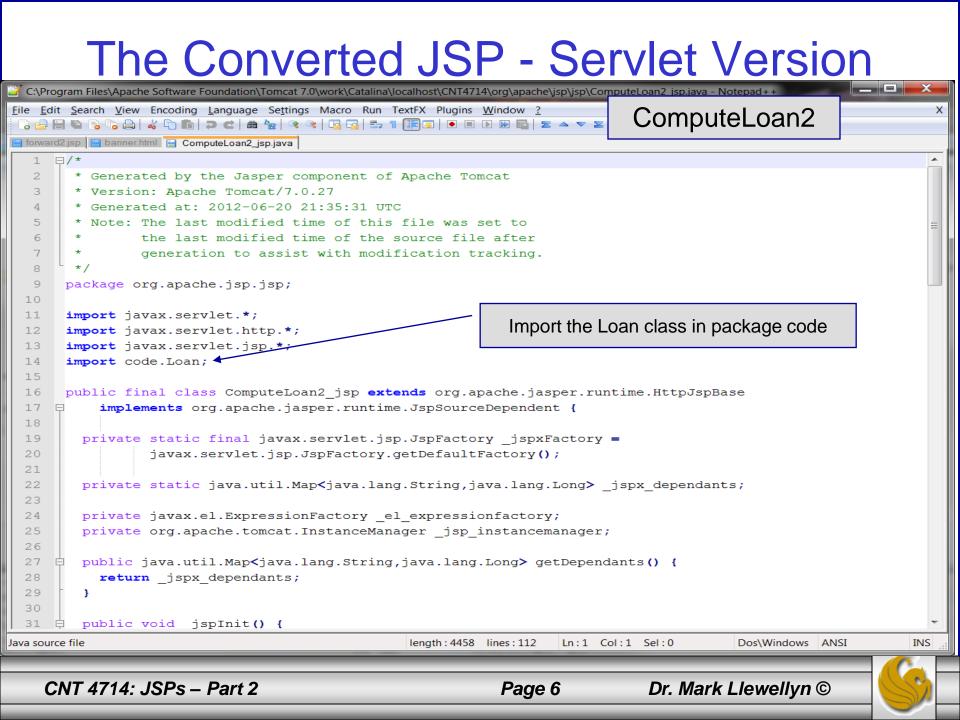

Servlet Versions of JSPs in Tomcat

<jsp: setProperty> Action

- Action <jsp: setProperty> sets JavaBean property values and is most useful for mapping request parameter values to JavaBean properties.
- Request parameters can be used to set properties of primitive types boolean, byte, char, short, int, long, float and double as well as java.lang types String, Boolean, Byte, Character, Short, Integer, Long, Float, and Double.
- The table on the following page summarizes the attributes of this action.

<jsp: setProperty> Action

Attribute Description	
name	The ID of the JavaBean for which a property (or properties) will be set.
property	The name of the property to set. Specifying "*" for this attribute specifies that the JSP should match the request parameters to the properties of the bean. For each request parameter that matches (i.e., the name of the request parameter is identical to the bean's property name), the corresponding property in the bean is set to the value of the parameter. If the value of the request parameter is "", the property value in the bean remains unchanged.
param	If the request parameter names do not match bean property names, this attribute can be used to specify which request parameter should be used to obtain the value for a specific bean property. This attribute is optional. If this attribute is omitted, the request parameter names must match the bean property names.
value	The value to assign to a bean property. The value typically is the result of a JSP expression. This attribute is particularly useful for setting bean properties that cannot be set using request parameters. This attribute is optional. If this attribute is omitted, the JavaBean property must be of a type that can be set using request parameters.

JSP Directives

- Directives are messages to the JSP container that enable the programmer to specify page settings, such as, the error page to invoke if an error occurs (page directive), including content from other resources (include directive), and to specify custom-tag libraries for use in a JSP (taglib directive).
- Directives are delimited by <%@ and %> and are processed at translation time. As such, directives do not produce any immediate output, because they are processed before the JSP accepts any requests.
- For our purposes here, the most important of these is the page directive, which we will make use of in the final example JSP. Some of the attributes of the page directive are shown on the next page.

JSP Page Directive Attributes

Attribute	Description			
import	Specifies a comma-separated list of fully qualified type names and/or packages that will be used in the current JSP.			
errorPage	Any exceptions in the current page that are not caught are sent to the error page for processing. The error-page implicit object exception references the original exception.			
extends	Specifies the class from which the translated JSP can inherit. This attribute must be a fully qualified class name.			

<jsp: useBean> Action

- Action <jsp: useBean> enables a JSP to manipulate a Java object. This action creates a Java object or locates an existing object for use in the JSP.
- The table on the following page summarizes the attributes of this action.
- If attributes class and beanName are not specified, the JSP container attempts to locate an existing object of the type specified in attribute type.
- Like JSP implicit objects, objects specified with this action have scope – page, request, session, or application – which indicates where they can be used in a web application. (Recall that objects with page scope are only accessible by the page in which they are defined. For example, all JSPs that process a single request can access an object in request scope.)

<jsp: useBean> Action

Attribute	Description			
id	The name used to manipulate the Java object with actions <jsp:setproperty> and <jsp:getproperty>. A variable of this name is also declared for use in JSP scripting elements. Case sensitive.</jsp:getproperty></jsp:setproperty>			
scope	The scope in which the Java object is accessible - page, request, session, or application. The default scope is page.			
class	The fully qualified class name of the Java object.			
beanName	The name of the JavaBean that can be used with method instantiate of class java.beans.Beans to load a JavaBean into memory.			
type	The type of the JavaBean. This can be the same type as the class attribute, a superclass of that type, or an interface implemented by that type. The defaul value is the same as for attribute class. A ClassCastException occurs if the Java object is not of the type specified with attribute type.			

A JSP Using <jsp: useBean> Action

- A common feature on many web sites is to place rotating advertisements on their webpages. Each visit to one of these pages results in a different advertisement being displayed in the user's web browser. Typically, when you click on the advertisement (or picture of a product) you are redirected to the website of the company that placed the advertisement or to the page that more completely describes the product.
- The next example illustrates a similar scenario, by rotating through a series of pictures (click the refresh button of your browser to simulate multiple logins or login from different browsers). In this example, I set it up to rotate through some pictures of some of my toys. If you click on a picture...you'll be redirected to the manufacturer's web page.

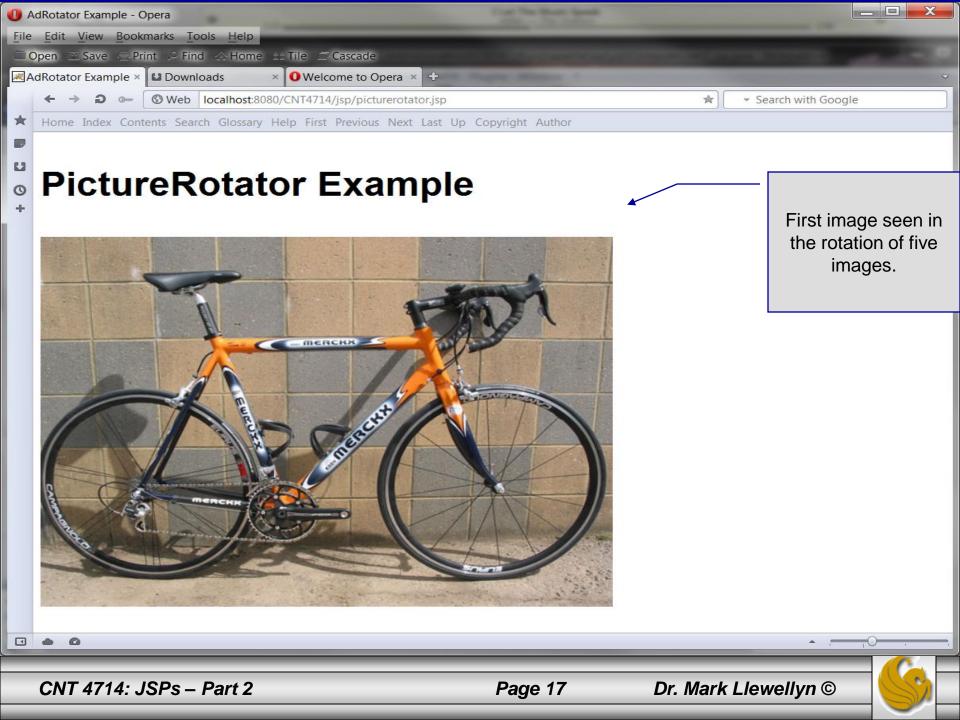

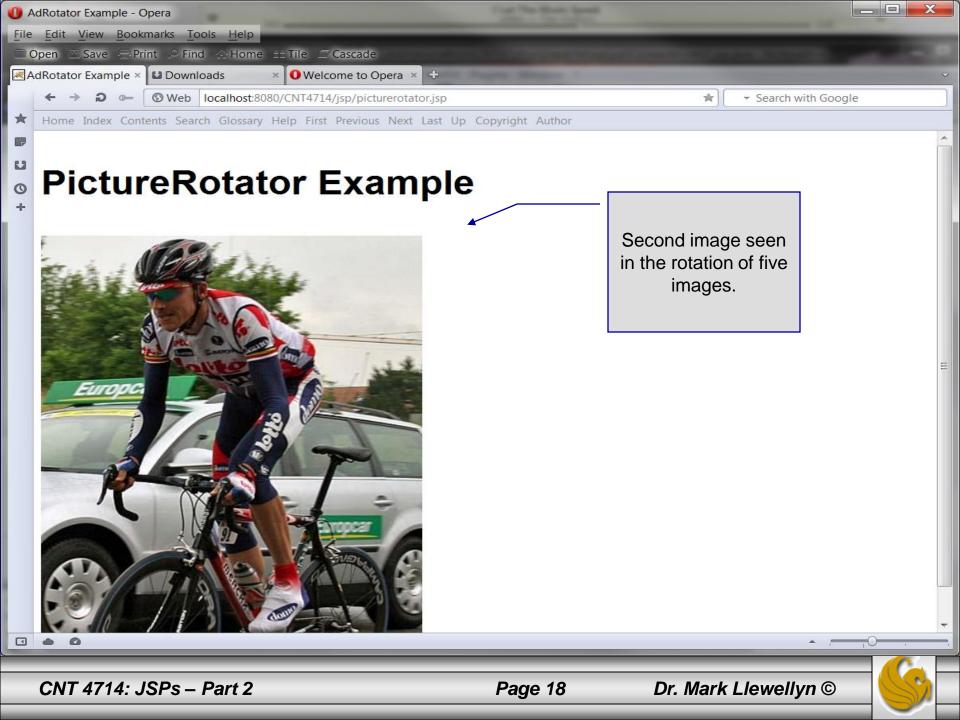

Dr. Mark Llewellyn ©

More Details On Using Beans

- The Rotator bean has three elements: getImage, getLink, and nextPic.
 - Method getImage returns the image file name for the picture to be displayed.
 - Method getLink returns the hyperlink to the manufacturer/supplier of the "toy".
 - Method nextPic updates the Rotator so that the next calls to getImage and getLink will return information for a different picture.
- Methods getImage and getLink each represent a read-only JavaBean property – image and link, respectively. These are read-only properties because no *set* methods are provided to change their values.
- Rotator keeps track of the current picture with its selectedIndex variable, which is updated by invoking method nextPic.

- JavaBeans were originally intended to be manipulated visually in visual development environments (often called builder tools or IDEs).
- Builder tools that support beans provide programmers with tremendous flexibility by allowing for the reuse and integration of existing disparate components that, in many cases, were never intended to be used together.
- When used in an IDE, JavaBeans adhere to the following coding conventions:
 - 1. Implements the Serializable interface.
 - 2. Provides a public no-argument (default) constructor.
 - 3. Provides get and/or set methods for properties (which are normally implemented as fields.)

- When used on the server side, such as within a JSP or a servlet, JavaBeans are less restricted.
 - Notice for example, that the Rotator bean does not implement the Serializable interface because there is no need to save and load the Rotator bean as a file.
- The JSP picturerotator.jsp (see page 6) obtains a reference to an instance of class Rotator. The id for the bean is rotator. The JSP uses this name to manipulate the bean. The scope of the object is session, so that every client will see the same sequence of pictures during their browsing sessions.

- When picturerotator.jsp receives a request from a new client, the JSP container creates the bean and stores it in that client's session (an HttpSession object).
- In each request to this JSP, the rotator reference which is created is used to invoke the Rotator bean's nextPic method. Therefore, each request will receive the next picture selected by the Rotator bean.
- Notice the two <jsp: getProperty> actions in the picturerotator.jsp file. One of these obtains the link property value from the bean, the other obtains the image property value.
 - Action <jsp: getProperty> has two attributes: name and property, which specify the bean object to manipulate and the property to get.

- Action <jsp: getProperty> has two attributes: name and property, which specify the bean object to manipulate and the property to get.
 - If the JavaBean object uses standard JavaBean naming conventions, the method used to obtain the link property value from the bean should be getLink.
 - Action <jsp: getProperty> invokes getLink on the bean referenced with rotator, converts the return value into a String and outputs the String as a part of the response to the client.

Dr. Mark Llewellyn ©

- The link and image properties can also be obtained with JSP expressions.
 - The action <jsp: getProperty> (see page 6 for location, the line looks like: <a href = "<jsp:getProperty name = "rotator" property = "link" />">) could be replaced with the expression: <%= rotator.getLink() %>
 - Similarly, the action <jsp: getProperty> (see page 6 for location, the line looks like: <img src = "<jsp:getProperty name = "rotator" property = "image" />" alt = "picture" />) could be replaced with the expression:

<%= rotator.getImage() %>

However, the benefit of using actions is that someone who is unfamiliar with Java can be told the name of a property and the name of a bean, and it is the action's responsibility to invoke the appropriate methods. The Java programmer's job is to create a bean that supports the capabilities required by the page designer.

Final JSP Example - GuestBook

- Our final JSP example will illustrate many of the techniques that we've covered in dealing with JDBC, servlets, and JSPs.
- This example constructs a simple MySQL database to maintain a guest book that includes a guest's first name, last name, and email address.
 - Once a guest enters their name into the guestbook, they will see a webpage containing all the guests in the guest book. Each email address is displayed as a hyperlink that makes it possible for guests to send email to another guest.
- This example illustrates the <jsp: setProperty> action, the JSP page directive, JSP error pages, and using JDBC from a JSP.

GuestBean.java

// GuestBean.java

// JavaBean to store data for a guest in the guest book.
package com.cnt4714.jsp.beans;

public class GuestBean

private String firstName; private String lastName; private String email;

```
// set the guest's first name
public void setFirstName( String name )
{
    firstName = name;
} // end method setFirstName
```

```
// get the guest's first name
public String getFirstName()
{
    return firstName;
```

} // end method getFirstName

This JavaBean maintains information for one guest.

Dr. Mark Llewellyn ©

GuestBean.java (cont.)

// set the guest's last name
public void setLastName(String name)

```
lastName = name;
} // end method setLastName
```

// get the guest's last name
public String getLastName()

return lastName;
} // end method getLastName

```
// set the guest's email address
public void setEmail( String address )
{
    email = address;
} // end method setEmail
```

```
// get the guest's email address
public String getEmail()
{
    return email;
    } // end method getEmail
} // end class GuestBean
```

CNT 4714: JSPs - Part 2

Page 30

GuestDataBean.java

// GuestDataBean.java

// Class GuestDataBean makes a database connection and supports

import com.sun.rowset.CachedRowSetImpl; // CachedRowSet implementation

// inserting and retrieving data from the database.

package com.cnt4714.jsp.beans;

import javax.sql.rowset.CachedRowSet;

import java.sql.SQLException;

This JavaBean performs the database access on behalf of the guestBookLogin.jsp

public class GuestDataBean

import java.util.ArrayList;

private CachedRowSet rowSet;

// construct TitlesBean object
public GuestDataBean() throws Exception

// load the MySQL driver Class.forName("com.mysql.jdbc.Driver");

// specify properties of CachedRowSet rowSet = new CachedRowSetImpl(); rowSet.setUrl("jdbc:mysql://localhost:3310/guestbook"); rowSet.setUsername("root"); rowSet.setPassword("root");

This application uses the CachedRowSet data model rather than the TableSet from our earlier JDBC application example.

Load JDBC driver and connect to database

Note this will cause compilation errors in Eclipse. Change the default settings in Eclipse : Windows -> Preferences -> Java -> Compiler -> Errors/Warnings -> Deprecated and restricted API -> Forbidden reference (access rules): -> change from error to warning.

GuestDataBean.java (cont.)

```
// obtain list of titles
    rowSet.setCommand(
        "SELECT firstName, lastName, email FROM guests" );
    rowSet.execute();
} // end GuestDataBean constructor
```

```
// return an ArrayList of GuestBeans
public ArrayList< GuestBean > getGuestList() throws SQLException
```

```
ArrayList< GuestBean > guestList = new ArrayList< GuestBean >();
```

```
rowSet.beforeFirst(); // move cursor before the first row
```

```
// get row data
while ( rowSet.next() )
{
```

```
GuestBean guest = new GuestBean();
```

```
guest.setFirstName( rowSet.getString( 1 ) );
guest.setLastName( rowSet.getString( 2 ) );
guest.setEmail( rowSet.getString( 3 ) );
```

```
guestList.add( guest );
} // end while
```

GuestDataBean.java

return guestList;

} // end method getGuestList

```
// insert a guest in guestbook database
public void addGuest( GuestBean guest ) throws SQLException
{
```

rowSet.moveToInsertRow(); // move cursor to the insert row

```
// update the three columns of the insert row
rowSet.updateString( 1, guest.getFirstName() );
rowSet.updateString( 2, guest.getLastName() );
rowSet.updateString( 3, guest.getEmail() );
rowSet.insertRow(); // insert row to rowSet
rowSet.moveToCurrentRow(); // move cursor to the current row
//rowSet.acceptChanges(); // force propagation of changes to database
} // end method addGuest
} // end class GuestDataBean
```

Note that the acceptChanges() method forces MySQL to perform a commit operation to make the changes permanent in the database. If your MySQL installation had autocommit set on (forcing automatic commits, you'll want to comment out this line, or in the reverse, if your MySQL has autocommit set off, you'll need to include this line of code.

Dr. Mark Llewellyn ©

GuestBookLogin.jsp

<?xml version = "1.0"?> <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">

<head>
```

```
<title>Guest Book Login</title>
<style type = "text/css">
body
```

```
font-family: tahoma, helvetica, arial, sans-serif;
```

GuestBookLogin.jsp is a modified version of our welcome1.jsp and welcome1 servlet that we've already seen. It displays a form that the guest uses to enter their information. When the form is submitted, GuestBookLogin.jsp is requested again so that it can ensure that all of the data is entered. If not, the form is regenerated until the guest enters all information. If all information is entered, then this JSP forwards the request to guestBookView.jsp to display the contents of the guest book.

> All uncaught exceptions are forwarded to guestBookErrorPage.jsp for processing.
