

Generally useful information.

- The notation $\mathbf{z} = \langle \mathbf{x}, \mathbf{y} \rangle$ denotes the pairing function with inverses $\mathbf{x} = \langle \mathbf{z} \rangle_1$ and $\mathbf{y} = \langle \mathbf{z} \rangle_2$.
- The minimization notation $\mu \mathbf{y} [\mathbf{P}(\dots, \mathbf{y})]$ means the least \mathbf{y} (starting at $\mathbf{0}$) such that $\mathbf{P}(\dots, \mathbf{y})$ is true. The bounded minimization (acceptable in primitive recursive functions) notation $\mu \mathbf{y} (\mathbf{u} \leq \mathbf{y} \leq \mathbf{v}) [\mathbf{P}(\dots, \mathbf{y})]$ means the least \mathbf{y} (starting at \mathbf{u} and ending at \mathbf{v}) such that $\mathbf{P}(\dots, \mathbf{y})$ is true. Unlike the text, I find it convenient to define $\mu \mathbf{y} (\mathbf{u} \leq \mathbf{y} \leq \mathbf{v}) [\mathbf{P}(\dots, \mathbf{y})]$ to be $\mathbf{v} + 1$, when no \mathbf{y} satisfies this bounded minimization.
- The tilde symbol, \sim , means the complement. Thus, set $\sim \mathbf{S}$ is the set complement of set \mathbf{S} , and predicate $\sim \mathbf{P}(\mathbf{x})$ is the logical complement of predicate $\mathbf{P}(\mathbf{x})$.
- A function \mathbf{P} is a predicate if it is a logical function that returns either $\mathbf{1}$ (**true**) or $\mathbf{0}$ (**false**). Thus, $\mathbf{P}(\mathbf{x})$ means \mathbf{P} evaluates to **true** on \mathbf{x} , but we can also take advantage of the fact that **true** is $\mathbf{1}$ and **false** is $\mathbf{0}$ in formulas like $\mathbf{y} \times \mathbf{P}(\mathbf{x})$, which would evaluate to either \mathbf{y} (if $\mathbf{P}(\mathbf{x})$) or $\mathbf{0}$ (if $\sim \mathbf{P}(\mathbf{x})$).
- A set \mathbf{S} is recursive if \mathbf{S} has a total recursive characteristic function $\chi_{\mathbf{S}}$, such that $\mathbf{x} \in \mathbf{S} \Leftrightarrow \chi_{\mathbf{S}}(\mathbf{x})$. Note $\chi_{\mathbf{S}}$ is a predicate. Thus, it evaluates to $\mathbf{0}$ (**false**), if $\mathbf{x} \notin \mathbf{S}$.
- When I say a set \mathbf{S} is re, unless I explicitly say otherwise, you may assume any of the following equivalent characterizations:
 1. \mathbf{S} is either empty or the range of a total recursive function $\mathbf{f}_{\mathbf{S}}$.
 2. \mathbf{S} is the domain of a partial recursive function $\mathbf{g}_{\mathbf{S}}$.
- If I say a function \mathbf{g} is partially computable, then there is an index \mathbf{g} (I know that's overloading, but that's okay as long as we understand each other), such that $\Phi_{\mathbf{g}}(\mathbf{x}) = \Phi(\mathbf{x}, \mathbf{g}) = \mathbf{g}(\mathbf{x})$. Here Φ is a universal partially recursive function. Moreover, there is a primitive recursive function **STP**, such that **STP**($\mathbf{x}, \mathbf{g}, \mathbf{t}$) is $\mathbf{1}$ (true), just in case \mathbf{g} , started on \mathbf{x} , halts in \mathbf{t} or fewer steps. **STP**($\mathbf{x}, \mathbf{g}, \mathbf{t}$) is $\mathbf{0}$ (false), otherwise. Finally, there is another primitive recursive function **VALUE**, such that **VALUE**($\mathbf{x}, \mathbf{g}, \mathbf{t}$) is $\mathbf{g}(\mathbf{x})$, whenever **STP**($\mathbf{x}, \mathbf{g}, \mathbf{t}$). **VALUE**($\mathbf{x}, \mathbf{g}, \mathbf{t}$) is defined but meaningless if $\sim \mathbf{STP}(\mathbf{x}, \mathbf{g}, \mathbf{t})$.
- The notation $\mathbf{f}(\mathbf{x}) \downarrow$ means that \mathbf{f} converges when computing with input \mathbf{x} , but we don't care about the value produced. In effect, this just means that \mathbf{x} is in the domain of \mathbf{f} .
- The notation $\mathbf{f}(\mathbf{x}) \uparrow$ means \mathbf{f} diverges when computing with input \mathbf{x} . In effect, this just means that \mathbf{x} is **not** in the domain of \mathbf{f} .
- The **Halting Problem** for any effective computational system is the problem to determine of an arbitrary effective procedure \mathbf{f} and input \mathbf{x} , whether or not $\mathbf{f}(\mathbf{x}) \downarrow$. The set of all such pairs is a classic re non-recursive one.
- The **Uniform Halting Problem** is the problem to determine of an arbitrary effective procedure \mathbf{f} , whether or not \mathbf{f} is an algorithm (halts on all input). The set of all such function indices is a classic non re one.
