

**Generally useful information.**

- The notation  $\mathbf{z} = \langle \mathbf{x}, \mathbf{y} \rangle$  denotes the pairing function with inverses  $\mathbf{x} = \langle \mathbf{z} \rangle_1$  and  $\mathbf{y} = \langle \mathbf{z} \rangle_2$ .
- The minimization notation  $\mu \mathbf{y} [\mathbf{P}(\dots, \mathbf{y})]$  means the least  $\mathbf{y}$  (starting at  $\mathbf{0}$ ) such that  $\mathbf{P}(\dots, \mathbf{y})$  is true. The bounded minimization (acceptable in primitive recursive functions) notation  $\mu \mathbf{y} (\mathbf{u} \leq \mathbf{y} \leq \mathbf{v}) [\mathbf{P}(\dots, \mathbf{y})]$  means the least  $\mathbf{y}$  (starting at  $\mathbf{u}$  and ending at  $\mathbf{v}$ ) such that  $\mathbf{P}(\dots, \mathbf{y})$  is true. Unlike the text, I find it convenient to define  $\mu \mathbf{y} (\mathbf{u} \leq \mathbf{y} \leq \mathbf{v}) [\mathbf{P}(\dots, \mathbf{y})]$  to be  $\mathbf{v} + 1$ , when no  $\mathbf{y}$  satisfies this bounded minimization.
- The tilde symbol,  $\sim$ , means the complement. Thus, set  $\sim \mathbf{S}$  is the set complement of set  $\mathbf{S}$ , and predicate  $\sim \mathbf{P}(\mathbf{x})$  is the logical complement of predicate  $\mathbf{P}(\mathbf{x})$ .
- A function  $\mathbf{P}$  is a predicate if it is a logical function that returns either **1 (true)** or **0 (false)**. Thus,  $\mathbf{P}(\mathbf{x})$  means  $\mathbf{P}$  evaluates to **true** on  $\mathbf{x}$ , but we can also take advantage of the fact that **true** is **1** and **false** is **0** in formulas like  $\mathbf{y} \times \mathbf{P}(\mathbf{x})$ , which would evaluate to either  $\mathbf{y}$  (if  $\mathbf{P}(\mathbf{x})$ ) or **0** (if  $\sim \mathbf{P}(\mathbf{x})$ ).
- A set  $\mathbf{S}$  is recursive if  $\mathbf{S}$  has a total recursive characteristic function  $\chi_{\mathbf{S}}$ , such that  $\mathbf{x} \in \mathbf{S} \Leftrightarrow \chi_{\mathbf{S}}(\mathbf{x})$ . Note  $\chi_{\mathbf{S}}$  is a predicate. Thus, it evaluates to **0 (false)**, if  $\mathbf{x} \notin \mathbf{S}$ .
- When I say a set  $\mathbf{S}$  is re, unless I explicitly say otherwise, you may assume any of the following equivalent characterizations:
  1.  $\mathbf{S}$  is either empty or the range of a total recursive function  $\mathbf{f}_{\mathbf{S}}$ .
  2.  $\mathbf{S}$  is the domain of a partial recursive function  $\mathbf{g}_{\mathbf{S}}$ .
- If I say a function  $\mathbf{g}$  is partially computable, then there is an index  $\mathbf{g}$  (I know that's overloading, but that's okay as long as we understand each other), such that  $\Phi_{\mathbf{g}}(\mathbf{x}) = \Phi(\mathbf{x}, \mathbf{g}) = \mathbf{g}(\mathbf{x})$ . Here  $\Phi$  is a universal partially recursive function. Moreover, there is a primitive recursive function **STP**, such that **STP**( $\mathbf{x}, \mathbf{g}, \mathbf{t}$ ) is **1** (true), just in case  $\mathbf{g}$ , started on  $\mathbf{x}$ , halts in  $\mathbf{t}$  or fewer steps. **STP**( $\mathbf{x}, \mathbf{g}, \mathbf{t}$ ) is **0** (false), otherwise. Finally, there is another primitive recursive function **VALUE**, such that **VALUE**( $\mathbf{x}, \mathbf{g}, \mathbf{t}$ ) is  $\mathbf{g}(\mathbf{x})$ , whenever **STP**( $\mathbf{x}, \mathbf{g}, \mathbf{t}$ ). **VALUE**( $\mathbf{x}, \mathbf{g}, \mathbf{t}$ ) is defined but meaningless if  $\sim \mathbf{STP}(\mathbf{x}, \mathbf{g}, \mathbf{t})$ .
- The notation  $\mathbf{f}(\mathbf{x}) \downarrow$  means that  $\mathbf{f}$  converges when computing with input  $\mathbf{x}$ , but we don't care about the value produced. In effect, this just means that  $\mathbf{x}$  is in the domain of  $\mathbf{f}$ .
- The notation  $\mathbf{f}(\mathbf{x}) \uparrow$  means  $\mathbf{f}$  diverges when computing with input  $\mathbf{x}$ . In effect, this just means that  $\mathbf{x}$  is **not** in the domain of  $\mathbf{f}$ .
- The **Halting Problem** for any effective computational system is the problem to determine of an arbitrary effective procedure  $\mathbf{f}$  and input  $\mathbf{x}$ , whether or not  $\mathbf{f}(\mathbf{x}) \downarrow$ . The set of all such pairs is a classic re non-recursive one.
- The **Uniform Halting Problem** is the problem to determine of an arbitrary effective procedure  $\mathbf{f}$ , whether or not  $\mathbf{f}$  is an algorithm (halts on all input). The set of all such function indices is a classic non re one.
