

The first three problems ask for sets of free or bound variable identifiers that occur bound in the statement above. Write the entire requested set in brackets. For example, write $\{V, W\}$, or if the requested set is empty, write $\{\}$.

1. Consider the following Oz statement in the kernel language.

```

local I in
  local J in
    I = 4020
    {DoIt I J}
    Q = J
  end
end

```

(a) (4 points) [Concepts] Write the entire set of the variable identifiers that occur free in the statement above.

(b) (4 points) [Concepts] Write the entire set of the variable identifiers that occur bound in the statement above.

2. Consider the following Oz statement.

```

Compose = proc {$ F G X R}
  local Temp in
    {G X Temp}
    {F Temp R}
  end
end
Add1 = proc {$ Y Result}
  local One in
    local Two in
      One = 1
      {Add Y One Result}
    end
  end
end
local Ret in
  local Three in
    Three = 3
    {Compose Add1 Id Three Ret}
  end
end

```

(a) (5 points) [Concepts] Write the entire set of the variable identifiers that occur free in the statement above.

(b) (10 points) [Concepts] Write the entire set of the variable identifiers that occur bound in the statement above.

3. [Concepts] [MapToLanguages]

(a) (3 points) In Java, will potential type errors always be reported before running the program? (Answer “yes” or “no”).

(b) (2 points) So what kind of type checking does Java have? (Give the technical term for it.)

4. [Concepts] [MapToLanguages] Consider the following Java method declaration.

```
public void find(int[] arr, int sought) {  
    for (int j = 0; j < len(arr); j++) {  
        if (f(arr[j]) == sought) { res = j; }  
    }  
}
```

(a) (3 points) Write below, in set brackets, the entire set of variable identifiers that occur free in the Java code above.

(b) (3 points) Write below, in set brackets, the entire set of variable identifiers that occur bound in the Java code above.

5. [Concepts] Consider the following Oz code.

```

local G in
  local Last in
    Last = proc {$ Ls Prev ?R}
      case Ls of
        H|T then
          %% Parts (c) and (e) ask about the call below (line 7)
          {Last T H R}
        else R = Prev
      end
    end
    G = Last
  end
  local Temp in
    local MyList in
      MyList = a|b|c|nil
      %% Parts (b), (d), and (e) ask about the call below (line 17)
      {G MyList a Temp}
      {Browse Temp}
    end
  end
end

```

- (a) (2 points) When the above code runs, what output, if any, appears in the browser?
- (b) (4 points) At the point of the call of G on line 17 (just below the second comment), is Last in the domain of the current environment? Give a brief explanation.
- (c) (4 points) Will the call to Last on line 7 work (just below the first comment) properly and make a successful call when the program runs? If so, briefly explain why, if not, then say what happens.
- (d) (3 points) Is the call on line 17 in the declarative kernel language? (Answer “yes” or “no” and briefly explain your answer.)
- (e) (3 points) Suppose Oz used dynamic scoping. In that case, would the calls on lines 17 and 7 both be successful when the program is run? If so, briefly explain why, if not, then say what would happen.

6. (15 points) [Concepts] Desugar the following Oz code into kernel syntax by expanding all syntactic sugars, so that your answer is an equivalent statement in the declarative kernel language. (Assume that the identifier `Result`, and the function identifiers `Product` and `ProdIter` are declared elsewhere.)

```
fun {Product Ls} {ProdIter Ls 1} end  
Result = {Product [3 4]}
```

7. (10 points) [Concepts] What happens when the following code executes in Oz? Briefly explain why that happens.

```
local SetIt It in  
  It = good  
  SetIt = proc {$ X}  
    It = X  
  end  
  {SetIt bad}  
  {Browse 'It is '#It}  
end
```

8. (10 points) [Concepts] What is the output, if any, of the following code in Oz? Briefly explain why that output appears.

```

local MyShoe Y in
  MyShoe = nike(model: mavrk num: 6.0 topcolor: black cost: 62.99)
  Y = 3
  case MyShoe of
    addidas(model: M num: N topcolor: C cost: Y) then {Browse first#M#N#C#Y}
  [] nike(model: M num: N topcolor: C cost: Y) then {Browse second#M#N#C#Y}
  [] nike(model: M num: N topcolor: C cost: Y) then {Browse third#M#N#C#Y}
  [] nike(model: M) then {Browse fourth#M}
  else {Browse none(Y)}
  end
end

```

9. [Concepts] Perl 6 (a new version of the programming language Perl 5) introduces a new kind of expression. As an example, one can write: `$c == 1|2|3` which means the same thing as the (more verbose) Perl 6 expression `$c == 1 or $c == 2 or $c == 3`.

(a) (5 points) What is the general term for such a shortening in programming languages?

(b) (10 points) Briefly describe one advantage of extending a language with such shortened forms of expressions.
