Fall 2008

Introduction to PHP – Part 1

Instructor : Dr. Mark Llewellyn
markl@cs.ucf.edu
HEC 236, 407-823-2790
<http://www.cs.ucf.edu/courses/cnt4714/fall2008>

School of Electrical Engineering and Computer Science
University of Central Florida

Introduction to PHP

- PHP is officially known as PHP: Hypertext Preprocessor and is very rapidly becoming the most popular server-side scripting language for creating dynamic web pages.
- PHP was created in 1994 by Rasmus Lerdorf (who currently works for Linuxcare, Inc. as a senior open-source researcher) to track users at his Web site. Lerdorf originally called it Personal Home Page Tools in a package he released in 1995. It eventually became an Apache Software Foundation project.
- PHP2 featured built-in database support and form handling. In 1997, PHP3 was released and featured a new parser which substantially increased performance and led to an explosion in PHP use.

Introduction to PHP (cont.)

- PHP4 featured the Zend Engine and was considerably faster and more powerful than its predecessors and further enhanced the popularity of PHP.
- The current release is PHP 5.2.6 and features the Zend Engine 2, which provides further increases in speed and functionality. You can download the latest version of PHP at www.php.net. For more details on the Zend Engine 2 see www zend com.
- Today more than 17 million domains utilize PHP technology.
- All of the examples we'll be looking at use the latest stable version of PHP which is 5.2.6 and was released May 1, 2008.

Introduction to PHP (cont.)

- The power of the Web resides not only in serving content to users, but also in responding to requests from users and generating Web pages with dynamic content.
- Interactivity between the user and the server has become a crucial part of Web functionality. While other languages can also perform these functions, PHP was written specifically for interacting with the Web.
- PHP code is embedded directly into XHTML documents. This allows the document author to write XHTML in a clear, concise manner, without having to use multiple print statements, as is necessary with other CGI-based languages.

Introduction to PHP (cont.)

- PHP script file names usually end with .php, although a server can be configured to handle other file extensions.
- To run a PHP script, PHP must first be installed on your system. Download PHP 5.2.6 from www.php.net. (Most recent version is 5.2.6.)
- Although PHP can be used from the command line, a Web server is required to take full advantage of the scripting language. I would suggest the Apache server available from www.apache.org. (Note: this is not the Tomcat server you've already used.) Current version is 2.2.8 which is a new major version change from the previous 2.0.xx versions (mostly in the areas of security).
- The easiest way to get this setup is to use WAMP Server. The current version of this is WAMP 2.0 which automatically loads and configures Apache 2.2.8, MySQL 5.0.51b and PHP 5.2.6. This is how I'll show you to get it set-up. Go to www.wampserver.com.

A screenshot of a Windows Internet Explorer browser window displaying the WampServer homepage. The URL in the address bar is http://www.wampserver.com/en/index.php. A blue callout box highlights the 'WAMP Server Homepage' text in the top right corner. Another blue callout box highlights the 'DOWNLOADS' link in the top navigation bar. On the left, there's a sidebar titled 'WAMP SERVER 2.0' with links like Localhost, phpMyAdmin, SQLiteManager, www directory, Apache, PHP, MySQL, and Quick Admin. The 'Quick Admin' option is currently selected. A blue callout box points to the 'Click here to download.' link in the main content area. The page also features advertisements for 'Web Server with PHP' and 'MySQL GUI'. The bottom status bar shows 'Internet | Protected Mode: Off' and '100%'. The overall theme is dark with light-colored text and icons.

```
37 #
38 # Listen: Allows you to bind Apache to specific IP addresses and/or
39 # ports, instead of the default. See also the <VirtualHost>
40 # directive.
41 #
42 # Change this to Listen on specific IP addresses as shown below to
43 # prevent Apache from glomming onto all bound IP addresses.
44 #
45 #Listen 12.34.56.78:80
46 #Listen 80
47 Listen 8081 ←

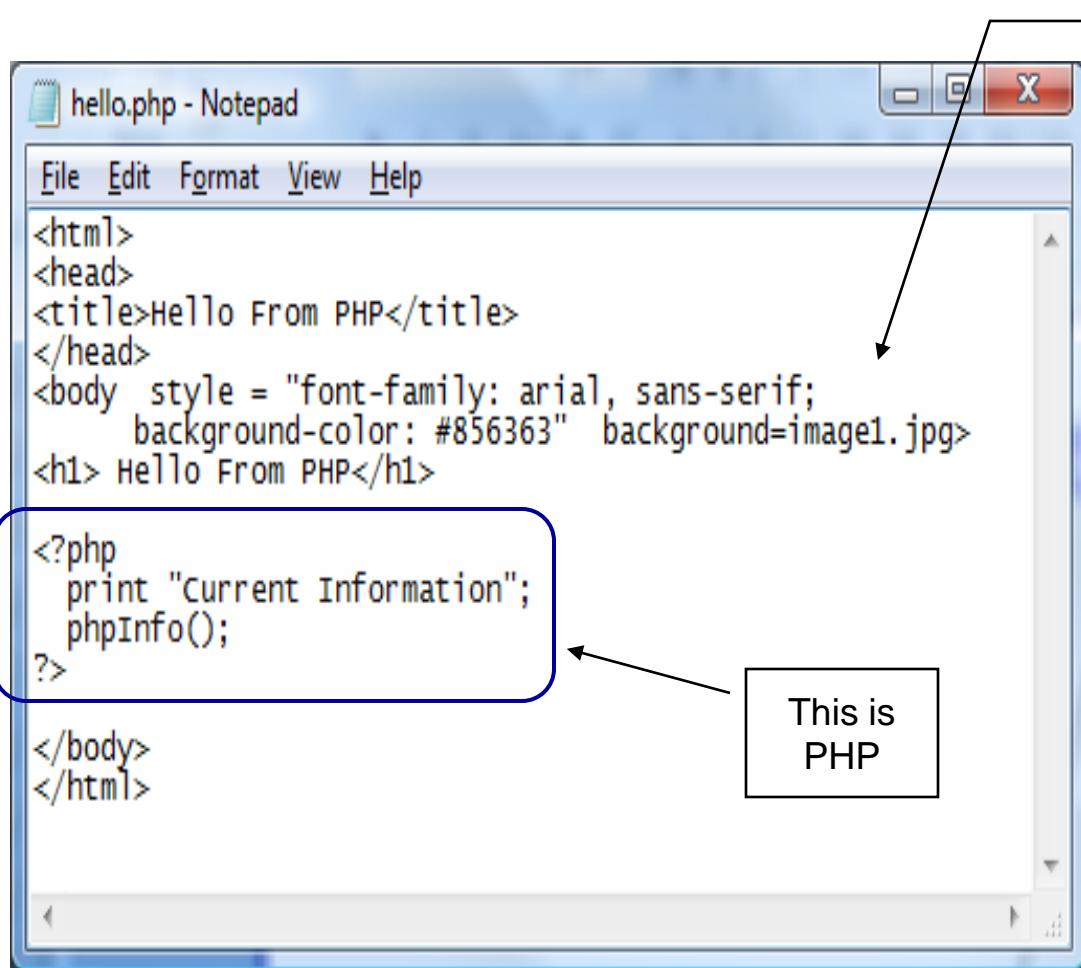

48
49 #
50 # Dynamic Shared Object (DSO) Support
51 #
52 # To be able to use the functionality of a module which was built as a DSO you
53 # have to place corresponding 'LoadModule' lines at this location so the
54 # directives contained in it are actually available before they are used.
55 # Statically compiled modules (those listed by 'httpd -l') do not need
56 # to be loaded here.
57 #
58 # Example:
59 # LoadModule foo_module modules/mod_foo.so
60 #
61 LoadModule actions_module modules/mod_actions.so
```

Normal text file nb char:18098 Ln:47 Col:7 Sel:0 Dos\Windows ANSI INS

Edit the httpd configuration file to have the Apache server listen on port 8081 instead of port 80 as is the default case.

A PHP Test Example

The screenshot shows a Windows Notepad window titled "hello.php - Notepad". The file contains the following PHP code:

```
<html>
<head>
<title>Hello From PHP</title>
</head>
<body style = "font-family: arial, sans-serif;
    background-color: #856363" background=image1.jpg>
<h1> Hello From PHP</h1>

<?php
    print "Current Information";
    phpInfo();
?>

</body>
</html>
```

A callout arrow points from the text "This is PHP" to the opening PHP tag on line 7.

Create this file named `hello.php` and save it to the `www` folder in the WAMP server. Then start the WAMP server, enter the URL:
<http://localhost:8081/hello.php> and you should see output similar to that shown on the next slide.

Hello From PHP - Windows Internet Explorer

A First PHP Example

- The following two pages illustrate a simple PHP “hello world” program.
- In PHP, code is inserted between the scripting delimiters `<?php` and `?>`. PHP code can be placed anywhere in XHTML markup, as long as the code is enclosed in these scripting delimiters.
- Place all of your XHTML and PHP files inside the WAMP www directory.

welcome.php Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"  
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">  
  
<!-- welcome.php -->  
<!-- XHTML file containing a PHP script. -->  
  
<?php  
    $name = "Mark";      //php declaration and assignment  
?>  
  
<html xmlns = "http://www.w3.org/1999/xhtml">  
  
    <!-- head section of document -->  
    <head>  
        <title>A Simple PHP Document</title>  
    </head>  
  
    <!-- body section of document -->  
    <body style = "font-size: 2em">  
        <hr>  
        <font color = blue><h1> Generating HTML From PHP </h1></font color>  
        <p>
```

PHP code declaring a variable.

welcome.php Example

```
<strong>
    <!--print variable name's value in the message-->
    {<?php
        print("This is your first crack at running a PHP script..."); 
        print("<HR>");
        print("Welcome to the world of PHP technology, ");
        ?>
        <font color = green>
            <?php
                print("$name");
            ?>
        </font color>
    </strong>
</p>
</body>
</html> <!-- end XHTML document -->
```

PHP code

PHP code

welcome.php Example Output

A screenshot of a Windows Internet Explorer window titled "A Simple PHP Document - Windows Internet Explorer". The address bar shows the URL "http://localhost:8081/welcome.php". The page content displays three lines of text generated by PHP:

Generating HTML From PHP
This is your first crack at running a PHP script...
Welcome to the world of PHP technology, Mark

The browser interface includes standard menu bars (File, Edit, View, Favorites, Tools, Help), toolbars (Google search, Bookmarks, Check, AutoLink), and status bars indicating "Protected Mode: Off" and "100% zoom".

Viewing Client/Server Environment Variables

- Knowledge of a client's execution environment is useful to system administrators who want to provide client-specific information.
- Environment variables contain information about a script's environment, such as the client's web browser, the HTTP host and the HTTP connection.
 - The table on the next page summarizes some of the superglobal arrays defined by PHP.
- The XHTML document on page 19 displays the values of the server's environment variables in a table. PHP stores the server variables and their values in the `$_SERVER` array. Iterating through the array allows one to view all of the server's environment variables.

Some Superglobal Environment Arrays

Variable Name	Description
<code>\$_SERVER</code>	Data about the currently running server.
<code>\$_ENV</code>	Data about the client's environment.
<code>\$_GET</code>	Data posted to the server by the <code>get</code> method.
<code>\$_POST</code>	Data posted to the server by the <code>post</code> method.
<code>\$_COOKIE</code>	Data contained in cookies on the client's computer.
<code>\$GLOBALS</code>	Array containing all global variables.

server.php Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<!-- server.php          -->
<!-- Program to display $_SERVER variables -->
<html xmlns = "http://www.w3.org/1999/xhtml">
  <head>
    <title>SERVER Variables Display</title>
  </head>

  <body style = "font-family: arial, sans-serif;
    background-color: #856363" background=image1.jpg>

    <table border = "0" cellpadding = "2" cellspacing = "0"
      width = "100%">
      <?php
        // print the key and value for each element
        // in the $_SERVER array
        foreach ( $_SERVER as $key => $value )
          print( "<tr><td bgcolor = \"#11bbff\">
            <strong>$key</strong></td> <td>$value</td></tr>" );
      ?>
    </table>
  </body>
</html>
```

Iterate through the
\$_SERVER array to list all
of the SERVER variables for
the current server on which
PHP is running.

Form Processing and Business Logic

- XHTML forms enable web pages to collect data from users and send it to a web server for processing.
- Interaction of this kind between users and web servers is vital to e-commerce applications. Such capabilities allow users to purchase products, request information, send and receive web-based email, perform on-line paging and take advantage of various other online services.
- The XHTML document on the next few pages collects information from a user for the purposes of adding them to a mailing list.
- The PHP file on page 23 validates the data entered by the user through the form and “registers” them in the mailing list database.

form.html Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"  
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">  
<!-- form.html -->  
<!-- Form for use with the form.php program -->
```

```
<html xmlns = "http://www.w3.org/1999/xhtml">  
    <head>  
        <title>Sample form to take user input in XHTML</title>  
    </head>  
    <body>
```

```
        <h1>This is a sample registration form.</h1>
```

Please fill in all fields and click Register.

```
<!-- post form data to form.php -->  
<form method = "post" action = "form.php">  
    <img src = "images/user.gif" alt = "User" /><br />  
    <span style = "color: blue">  
        Please fill out the fields below.<br />  
    </span>  
<!-- create four text boxes for user input -->  
    <img src = "images/fname.gif" alt = "First Name" />  
    <input type = "text" name = "fname" /><br />
```

This XHTML document generates the form that the user will submit to the server via form.php

```
<img src = "images/lname.gif" alt = "Last Name" />
<input type = "text" name = "lname" /><br />
<img src = "images/email.gif" alt = "Email" />
<input type = "text" name = "email" /><br />
<img src = "images/phone.gif" alt = "Phone" />
<input type = "text" name = "phone" /><br />
<span style = "font-size: 10pt">
    Must be in the form (555)555-5555</span>
<br /><br />
<img src = "images/downloads.gif"
    alt = "Products" /><br />

<span style = "color: blue">
    Which publication would you like information about?
</span><br />

<!-- create drop-down list containing magazine names -->
<select name = "magazine">
    <option>Velo-News</option>
    <option>Cycling Weekly</option>
    <option>Pro Cycling</option>
    <option>Cycle Sport</option>
        <option>RadSport</option>
        <option>Mirror du Cyclisme</option>
</select>
<br /><br />
```

```
<img src = "images/os.gif" alt = "Operating System" />
<br /><span style = "color: blue">
    Which operating system are you currently using?
<br /></span>
<!-- create five radio buttons -->
<input type = "radio" name = "os" value = "Windows XP"
    checked = "checked" />
    Windows XP
<input type = "radio" name = "os" value =
    "Windows 2000" />
    Windows 2000
<input type = "radio" name = "os" value =
    "Windows 98" />
    Windows 98<br />
<input type = "radio" name = "os" value = "Linux" />
    Linux

<input type = "radio" name = "os" value = "Other" />
    Other<br />

    <!-- create a submit button -->
    <input type = "submit" value = "Register" />
</form>

</body>
</html>
```

form.php Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"  
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```

```
<!-- form.php -->
```

```
<!-- Read information sent from form.html -->
```

```
<html xmlns = "http://www.w3.org/1999/xhtml">  
    <head>  
        <title>Form Validation</title>  
    </head>  
    <body style = "font-family: arial,sans-serif">
```

```
<?php
```

```
extract($_POST);
```

```
// determine whether phone number is valid and print an error message if not
```

```
if ( !ereg( "^([0-9]{3})[0-9]{3}-[0-9]{4}$",
```

```
    $phone ) {
```

```
    print( "<p><span style = \"color: red; font-size: 2em\">
```

```
        INVALID PHONE NUMBER:</span><br />
```

```
        A valid phone number must be in the form
```

```
        <strong>(555)555-5555</strong><br />
```

```
        <span style = \"color: blue\">
```

```
        Click the Back button, enter a valid phone number and resubmit.<br /><br />
```

```
        Thank You.</span></p></body></html>" );
```

```
    die(); // terminate script execution
```

```
}
```

```
?>
```

Function extract
(associativeArray) creates a
variable-value pair
corresponding to each key-
value pair in the associative
array \$_POST.

See page 36 for
explanation of regular
expressions.

Function die() terminates script execution.
An error has occurred, no need to continue.

```

How the Form Example Works

- The action attribute of the form element, indicates that when the user clicks the Register button, the form data will be posted to form.php for processing.
- Using method = “post” appends the form data to the browser request that contains the protocol (i.e., HTTP) and the requested resource’s URL. Scripts located on the web server’s machine (or accessible through the network) can access the form data sent as part of the request.
- Each of the form’s input fields are assigned a unique name. When Register is clicked, each field’s name and value are sent to the web server.
- Script form.php then accesses the value for each specific field through the global array \$_POST.

How the Form Example Works (cont.)

- The superglobal arrays are associative arrays predefined by PHP that hold variable acquired from the user input, the environment, or the web server and are accessible in any variable scope.
 - If the information from the form had been submitted via the HTTP method get, then the superglobal array `$_GET` would contain the name-value pairs.
- Since the HTML form and the PHP script “communicate” via the name-value pairs, it is a good idea to make the XHTML object names meaningful so that the PHP script that retrieves the data is easier to understand.

Register_globals

- In PHP versions 4.2 and higher, the directive register_globals is set to Off by default for security reasons.
- Turning off register_globals means that all variables sent from an XHTML form to a PHP document now must be accessed using the appropriate superglobal array (either \$_POST or \$_GET).
- When this directive was turned On, as was the default case in PHP versions prior to 4.2, PHP created an individual global variable corresponding to each form field.

Validation of Form Generated Data

- The form example illustrates an important concept in the validation of user input. In this case, we simply checked the validity of the format of the telephone number entered by the client user.
- In general, it is crucial to validate information that will be entered into database or used in mailing lists. For example, validation can be used to ensure that credit-card numbers contain the proper number of digits before the numbers are encrypted to a merchant.
- In this case, the form.php script is implementing the **business logic** or **business rules** for our application.

Pattern Matching in PHP

- For powerful string comparisons (pattern matching), PHP provides functions `ereg` and `preg_match`, which use regular expressions to search a string for a specified pattern.
- Function `ereg` uses **Portable Operating System Interface (POSIX) extended regular expressions**.
 - POSIX-extended regular expressions are a standard to which PHP regular expression conform.
- Function `preg_match` provides **Perl-compatible regular expressions**.
- Perl-compatible regular expressions are more widely used than POSIX regular expressions. PHP's support for Perl-compatible regular expressions eases migration from Perl to PHP. The following examples illustrates these concepts.

expression.php - Example

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<!-- expression.php -->
<!-- Using regular expressions -->
<html xmlns = "http://www.w3.org/1999/xhtml">
<head>
    <title>Regular expressions</title>
</head>
<body>
    <?php
        $search = "Now is the time";
        print( "Test string is: '$search'<br /><br />" );
        // call function ereg to search for pattern 'Now' in variable search
        if ( ereg( "Now", $search ) )
            print( "String 'Now' was found.<br />" );
        // search for pattern 'Now' in the beginning of the string
        if ( ereg( "^Now", $search ) )
            print( "String 'Now' found at beginning of the line.<br />" );
        // search for pattern 'Now' at the end of the string
        if ( ereg( "Now$", $search ) )
            print( "String 'Now' was found at the end of the line.<br />" );
```

^ matches at beginning
of a string

\$ matches at end of a
string

```

// search for any word ending in 'ow'
if ( ereg( "[[:<:]]([a-zA-Z]*ow)[[:>:]]", $search,
$match ) )
print( "Word found ending in 'ow': " .
$match[ 1 ] . "<br />" );

// search for any words beginning with 't'
print( "Words beginning with 't' found: ");

while ( eregi( "[[:<:]](t[[:alpha:]]+)[[:>:]]",
$search, $match ) ) {
print( $match[ 1 ] . " " );

// remove the first occurrence of a word beginning
// with 't' to find other instances in the string
$search = ereg_replace( $match[ 1 ], "", $search );
}

print( "<br />" );
?>
</body>
</html>

```

Uses a regular expression to match a word ending in “ow”.

Output From expression.php - Example

A screenshot of a Windows Internet Explorer window titled "Regular expressions - Windows Internet Explorer". The address bar shows the URL "http://localhost:8081/expression.php". The page content displays the following text:

```
Test string is: 'Now is the time'  
String 'Now' was found.  
String 'Now' found at beginning of the line.  
Word found ending in 'ow': Now  
Words beginning with 't' found: the time
```

The browser interface includes a menu bar (File, Edit, View, Favorites, Tools, Help), a toolbar with various icons, and status bars at the bottom indicating "Protected Mode: Off" and "100%".

Verifying a Username and Password Using PHP

- It is often the case that a private website is created which is accessible only to certain individuals.
- Implementing privacy generally involves username and password verification.
- In the next example, we'll see an XHTML form that queries a user for a username and password. The fields **USERNAME** and **PASSWORD** are posted to the PHP script `verify.php` for verification.
 - For simplicity, data is not encrypted before sending it to the server.
 - For more information on PHP encryption functions visit:
<http://www.php.net/manual/en/ref.mcrypt.php>

How password.php Works

- The PHP script password.php verifies the client's username and password by querying a database. For this example, the "database" of usernames and passwords is just a text file (for simplicity). Existing users are validated against this file, and new users are appended to it.
- Whether we are dealing with a new user is determined by calling function `isset` to test if variable `$NewUser` has been set.
- When the user submits the password.html form to the server, they click either **Enter** or **New User** button. After calling function `extract`, either variable `$NewUser` or `$Enter` is created depending on which button was selected. If `$NewUser` has not been set, we assume the user clicked **Enter**.

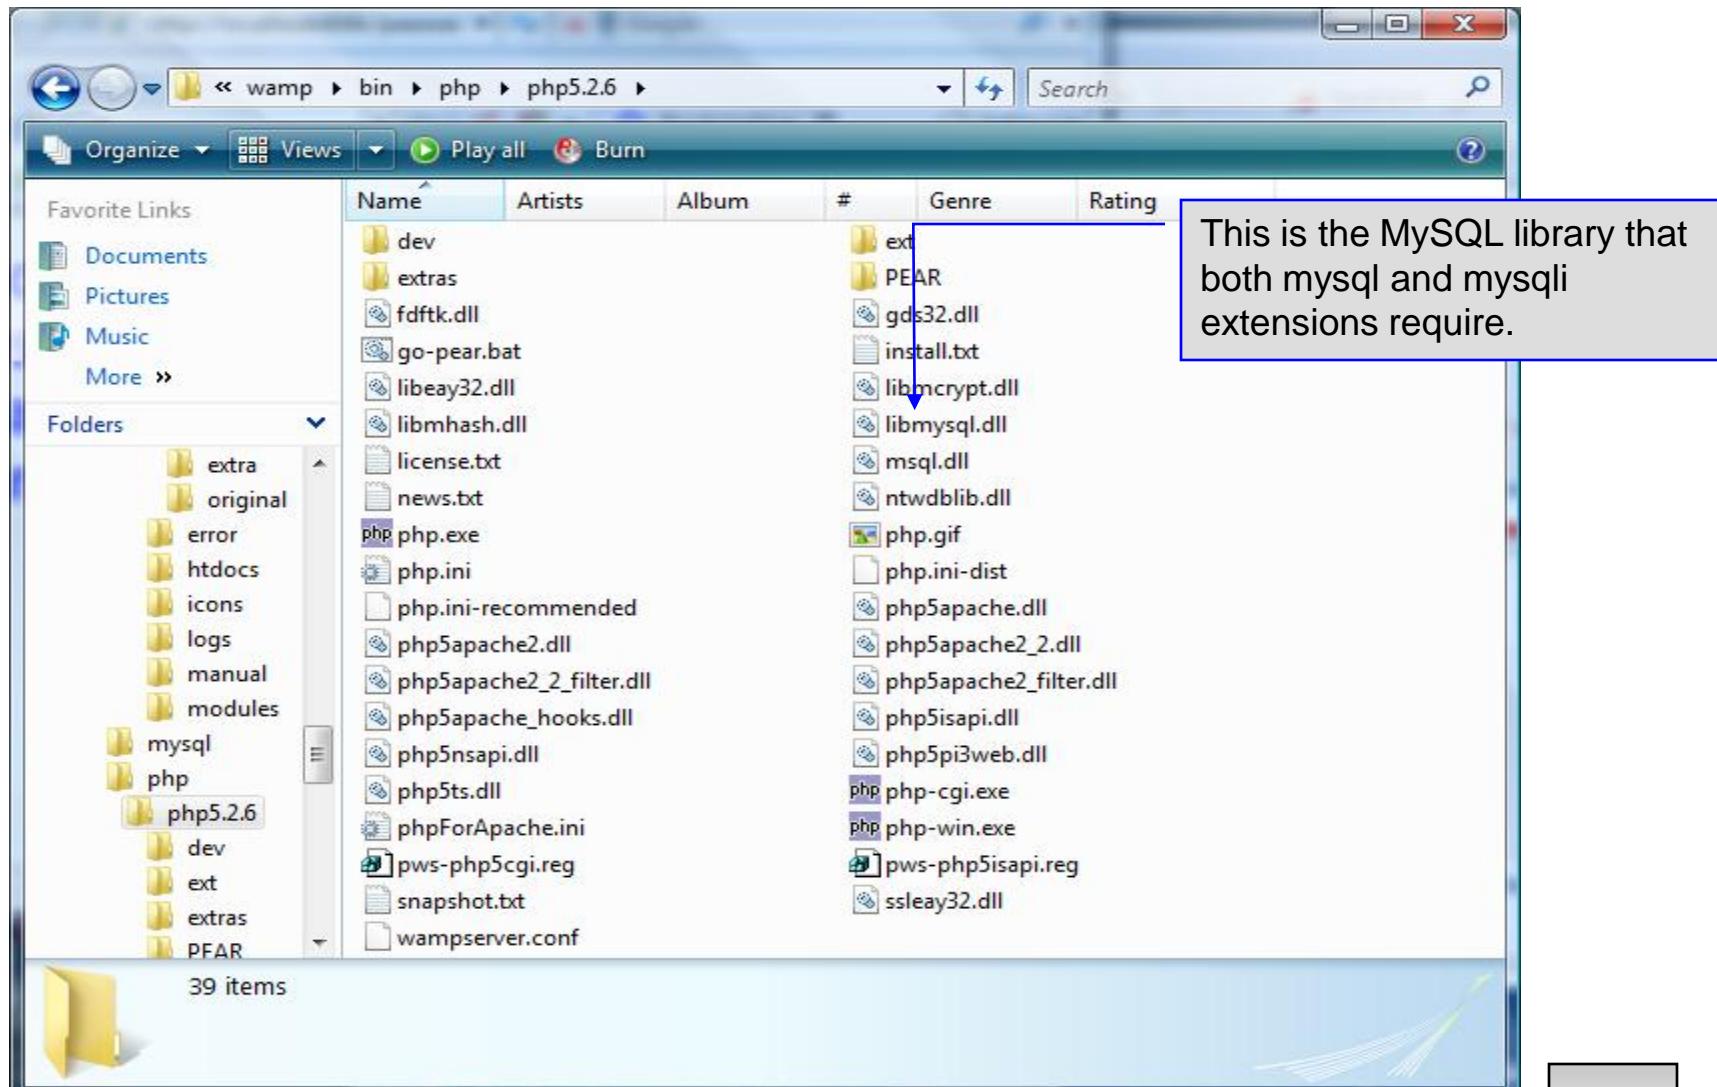

PHP and Database Connectivity

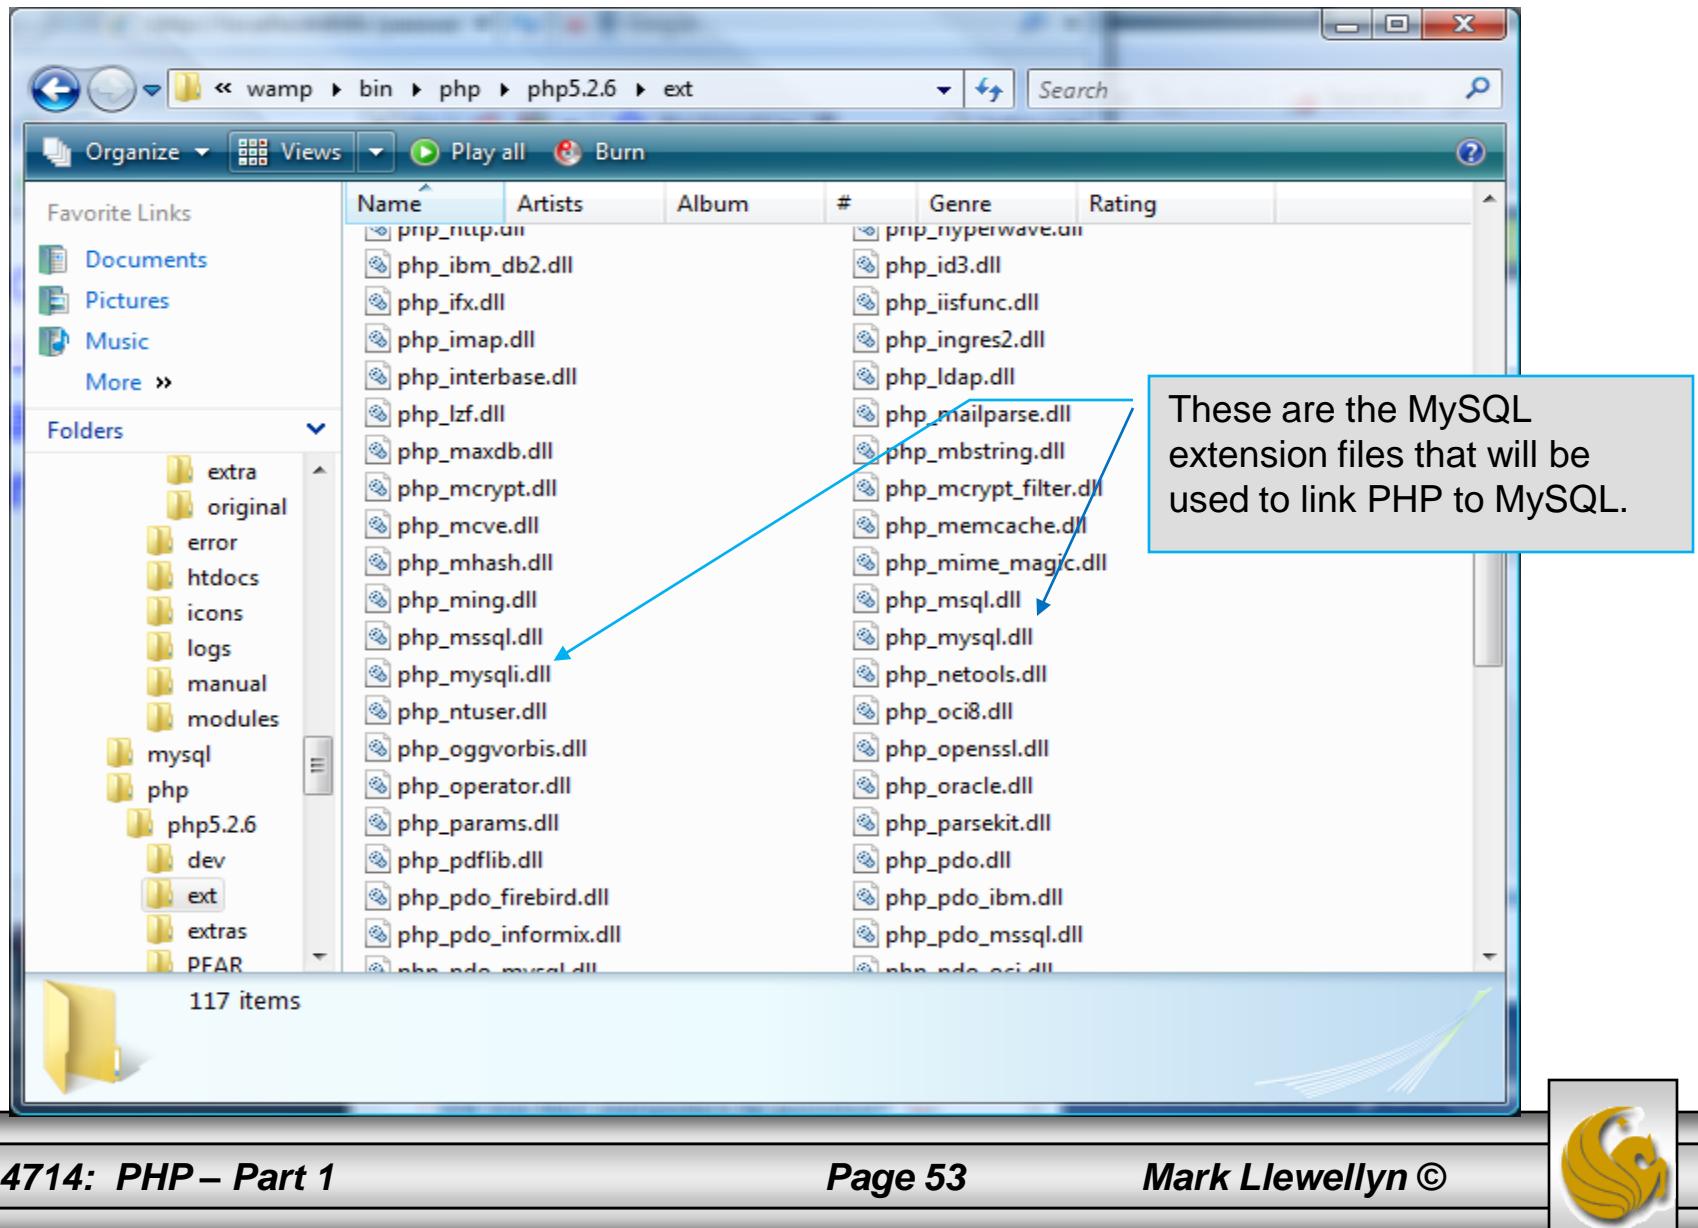

- PHP offers built-in support for a wide variety of database systems from Unix DBM through relational systems such as MySQL to full size commercial systems like Oracle.
- We'll continue to use MySQL as the underlying database system so that you can easily compare the work we've done with MySQL using Java servlets and JSPs.
- Before you go any further in these notes you must configure PHP to access MySQL databases. Beginning with PHP 5, MySQL is not enabled by default in PHP, nor is the MySQL library bundled with PHP.
 - Versions of MySQL greater than 4.1.0 use MySQLi extensions.
 - Versions of MySQL less than 4.1.0 use MySQL extensions.

PHP and Database Connectivity (cont.)

PHP and Database Connectivity (cont.)

A screenshot of a Windows operating system's file explorer window. The path in the address bar is: wamp \ bin \ php \ php5.2.6 \ ext. The left sidebar shows various folders like extra, original, error, htdocs, icons, logs, manual, modules, mysql, php, and others. The main pane displays a list of DLL files under the heading "Name". A blue callout box points to the "php_mysql.dll" file in the list, which is located near the bottom of the list. The list includes many other MySQL-related files such as php_mysqli.dll, php_mssql.dll, php_myisam.dll, etc. The status bar at the bottom indicates there are 117 items in the folder.

These are the MySQL extension files that will be used to link PHP to MySQL.

PHP and Database Connectivity (cont.)

A screenshot of a Windows Notepad window titled "php - Notepad". The window contains the contents of a PHP configuration file, specifically the "php.ini" file. The file lists numerous PHP extension directives, each starting with a semi-colon (comment character). A blue arrow points from the text "These two extensions will not be commented out." in the callout box to the line "extension=php_pdo_sqlite.dll".

```
;extension=php_ldap.dll  
;extension=php_mcrypt.dll  
;extension=php_mhash.dll  
;extension=php_mime_magic.dll  
;extension=php_ming.dll  
;extension=php_mssql.dll  
;extension=php_msqli.dll  
extension=php_mysql.dll  
extension=php_myqli.dll  
;extension=php_oc18.dll  
;extension=php_openssl.dll  
;extension=php_oracle.dll  
;extension=php_pdf.dll  
;extension=php_pgsql.dll  
;extension=php_shmop.dll  
;extension=php_snmp.dll  
;extension=php_sockets.dll  
;extension=php_sybase_ct.dll  
;extension=php_tidy.dll  
;extension=php_xmlrpc.dll  
;extension=php_xsl.dll  
;extension=php_zip.dll  
extension=php_pdo.dll  
extension=php_pdo_sqlite.dll  
;extension=php_pdo_firebird.dll  
;extension=php_pdo_mssql.dll  
;extension=php_pdo_mysql.dll  
;extension=php_pdo_oci.dll  
;extension=php_pdo_oci8.dll  
;extension=php_pdo_odbc.dll  
;extension=php_pdo_pgsql.dll
```

These two extensions will not be commented out. At loadtime, these extensions will now be included in the PHP environment, provided that the file php.ini is set..

PHP and Database Connectivity (cont.)

- Now that you have PHP set to accept MySQL extensions, let's connect to the bike database that we used for examples with Java servlets and JSPs.
- The following example is a simple database connection process in PHP where the client interacts with the database from an XHTML form that simply asks them to select which attributes from the bikes table that they would like to display. This is done through the data.html file.
- When the client clicks the submit query button, the database.php script executes by connecting to the database, posting the query, retrieving the results, and displaying them to the client.

data.html

Client side

Execution of data.html – Client side

The screenshot shows a Windows Internet Explorer window titled "Sample Database Query From PHP - Windows Internet Explorer". The address bar contains "http://localhost:8081/data.html". The main content area displays a form with the following text:
Querying a MySQL database from a PHP Script.
Select a field to display:
A dropdown menu is open, listing the following options:

- *
- *
- bikename
- size
- color
- cost
- purchased
- mileage

A blue arrow points from the explanatory text below to the dropdown menu.

Execution of data.html (client side of the application) showing the drop-down menu for the client to select the attributes for the query.

When the selection is made and the **Send Query** button is clicked the results on the following page will be displayed.

Cookies

- A **cookie** is a text file that a Web site stores on a client's computer to maintain information about the client during and between browsing sessions.
- A Web site can store a cookie on a client's computer to record user preferences and other information that the Web site can retrieve during the client's subsequent visits. For example, many Web sites use cookies to store client's zipcodes. The Web site can retrieve the zipcode from the cookie and provide weather reports and news updates tailored to the user's region.
- Web sites also use cookies to track information about client activity. Analysis of information collected via cookies can reveal the popularity of Web sites or products.

Cookies (cont.)

- Marketers use cookies to determine the effectiveness of advertising campaigns.
- Web sites store cookies on users' hard drives, which raises issues regarding security and privacy. Web sites should not store critical information, such as credit-card numbers or passwords, in cookies, because cookies are just text files that anyone can read.
- Several cookie features address security and privacy concerns. A server can access only the cookies that it has placed on the client.
- A cookie has an expiration date, after which the Web browser deletes it.

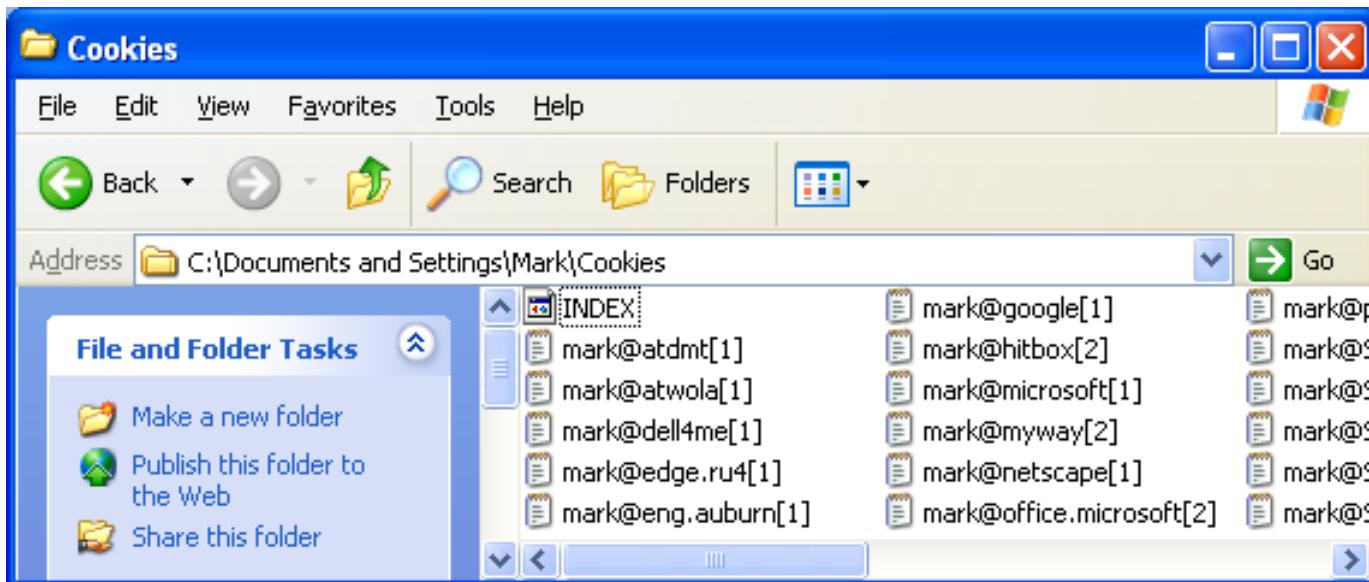

Cookies (cont.)

- Users who are concerned about the privacy and security implications of cookies can disable them in their Web browsers. However, the disabling of cookies can make it impossible for the user to interact with Web sites that rely on cookies to function properly.
- Information stored in the cookie is sent to the Web server from which it originated whenever the user requests a Web page from that particular server. The Web server can send the client XHTML output that reflects the preferences or information that is stored in the cookie.
- The location of the cookie file varies from browser to browser. Internet Explorer places cookies in the Cookies directory located at C:\Documents and Settings\...\Cookies

Cookies (cont.)

- After a cookie is created, a text file is added to this directory. While the name of the file will vary from user to user a typical example is shown below.

- The contents of a cookie are shown on page 74.

Cookies (cont.)

- Now let's create the code necessary to create our own cookie.
- In this example, a PHP script is invoked from a client-side HTML document. The HTML document creates a form for the user to enter the information that will be stored in the cookie. (Often the information that is stored in a cookie will be extracted from several different areas and may involve tracking the client's actions at the Web site.)
- Once the user has entered their information, when they click the **Write Cookie** button, the `cookies.php` script executes.
- The XHTML document and the PHP script are shown on the next pages. The XHTML document `cookies.html` is on page 36 and the PHP script `cookies.php` appears on page 37.

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"

      <strong>Height:</strong><br />
      <input type = "text" name = "HEIGHT" /><br />
      <strong>Favorite Color:</strong><br />
      <input type = "text" name = "COLOR" /><br />
      <p>
        <input type = "submit" value = "Write Cookie" style = "background-color: #0000FF;
          color: yellow; font-weight: bold" /></p>
    </form>
  </body> </html>
```

```
<?php
// cookies.php
// Program to write a cookie to a client's machine
extract( $_POST );
// write each form field's value to a cookie and set the
// cookie's expiration date
setcookie( "Name", $NAME, time() + 60 * 60 * 24 * 5 );
setcookie( "Height", $HEIGHT, time() + 60 * 60 * 24 * 5 );
setcookie( "Color", $COLOR, time() + 60 * 60 * 24 * 5 );
?>
```

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```

```
<html xmlns = "http://www.w3.org/1999/xhtml">
<head>    <title>Cookie Saved</title>  </head>
<body style = "font-family: arial, sans-serif", background=image1.jpg>
<p><b>The cookie has been set with the following data:</b></p>
<!-- print each form field's value -->
<br /><span style = "color: blue">Name:</span>
<?php print( $NAME ) ?><br />
<span style = "color: blue">Height:</span>
<?php print( $HEIGHT ) ?><br />
<span style = "color: blue">Favorite Color:</span>

</span><br />
<p>Click <a href = "readCookies.php">here</a> to read the saved cookie.</p>
</body> </html>
```

Function setcookie sets the cookies to the values passed from the cookies.html form. Function setcookie prints XHTML header information and therefore it needs to be called before any other XHTML (including comments) is printed.

The third argument to setcookie is optional and indicates the expiration date of the cookie. In this case it is set to expire 5 days from the current time. Function time returns the current time and then we add to this the number of seconds after which the cookie is to expire.

Cookies (cont.)

A screenshot of a Windows Internet Explorer window titled "Writing a cookie to the client computer - Windows Internet Explorer". The address bar shows the URL "http://localhost:8081/cookies.html". The page content is a form with the following fields:

- Name:
- Height:
- Favorite Color:

Below the form is a blue button labeled "Write Cookie". Above the "Write Cookie" button, the text "Click Write Cookie to save your cookie data." is displayed in bold black font.

A blue callout box with a black border and a black arrow points from the text "HTML form generated by cookies.html" to the "Write Cookie" button area.

The status bar at the bottom of the browser window shows "Done", "Internet | Protected Mode: Off", "100%", and a zoom control.

Cookies (cont.)

The screenshot shows a Windows Internet Explorer window titled "Cookie Saved - Windows Internet Explorer". The address bar displays "http://localhost:8081/cookies.php". The page content is as follows:

The cookie has been set with the following data:

Name: Mark Llewellyn
Height: 6' 3"
Favorite Color: blue

Click [here](#) to read the saved cookie.

A blue arrow points from the text "Output from cookies.php script showing the values in the newly created cookie." to the "Favorite Color: blue" line in the page content.

Output from
cookies.php script
showing the values in
the newly created
cookie.

Cookies (cont.)

- Once the cookie has been created, the cookies.php script gives the user the chance to view the newly created cookie by invoking the readCookies.php script from within the cookies.php script by clicking on the link.
- The readCookies.php script code is illustrated on the next page followed by the output from the execution of this PHP script.

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"  
 "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">  
  
<!-- readCookies.php -->  
<!-- Program to read cookies from the client's computer -->  
  
<html xmlns = "http://www.w3.org/1999/xhtml">  
 <head><title>Read Cookies</title></head>  
  
 <body style = "font-family: arial, sans-serif" background=image1.jpg>  
   <p>  
     <strong> The following data is saved in a cookie on your computer.  
   </strong>  
   </p>  
   <table border = "5" cellspacing = "0" cellpadding = "10">  
     <?php  
       // iterate through array $_COOKIE and print  
       // name and value of each cookie  
       foreach ( $_COOKIE as $key => $value )  
         print( "<tr>  
           <td bgcolor=\"#F0E68C\">$key</td>  
           <td bgcolor=\"#FFA500\">$value</td>  
           </tr>" );  
     ?>  
   </table>  
</body> </html>
```

Superglobal array holding cookie.

Cookies (cont.)

The screenshot shows a Windows Internet Explorer window titled "Read Cookies - Windows Internet Explorer". The address bar contains the URL "http://localhost:8081/readCookies.php". The page content displays the following text and table:

The following data is saved in a cookie on your computer.

Name	Mark Llewellyn
Height	6' 3"
Color	blue

A blue arrow points from the text "Output from the readCookies.php script." to the table on the page.

Output from the readCookies.php script.

Done Internet | Protected Mode: Off 100% ▾

Cookies (cont.)

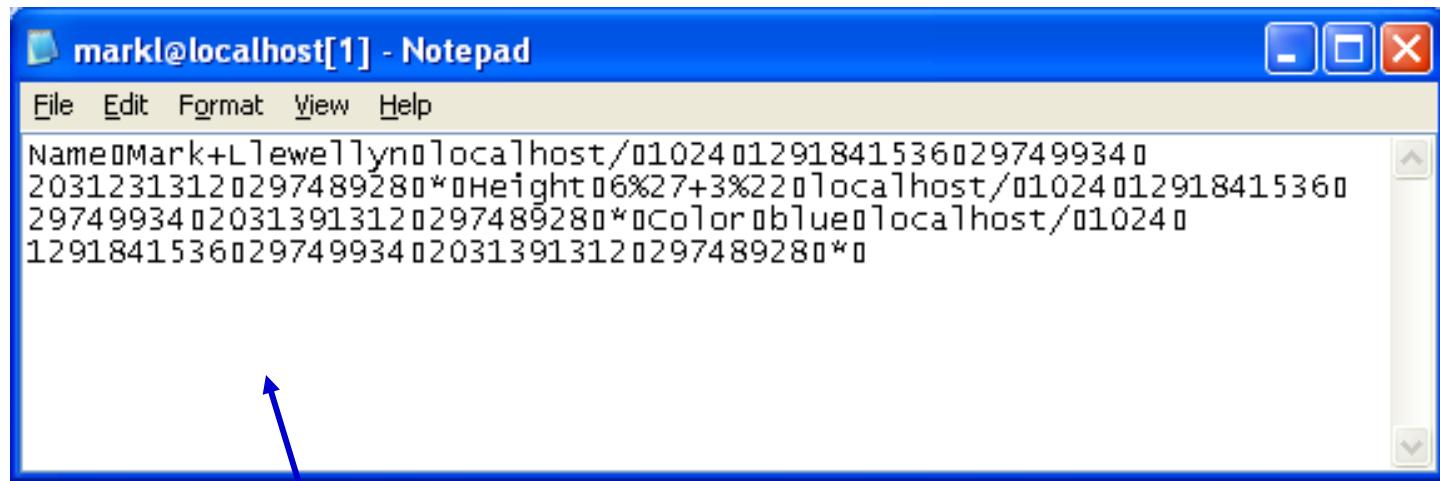

The screenshot shows a Windows Internet Explorer window displaying the Apache Environment. The title bar reads "Hello From PHP - Windows Internet Explorer". The address bar shows "http://localhost:8081/hello.php". The main content area displays a table of environment variables:

Variable	Value
HTTP_ACCEPT	*/*
HTTP_ACCEPT_LANGUAGE	en-us
HTTP_UA_CPU	x86
HTTP_ACCEPT_ENCODING	gzip, deflate
HTTP_USER_AGENT	Mozilla/4.0 (compatible; MSIE 7.0; Windows NT 6.0; SLCC1; .NET CLR 2.0.50727; .NET CLR 3.0.04506; InfoPath.2)
HTTP_HOST	localhost:8081
HTTP_CONNECTION	Keep-Alive
HTTP_COOKIE	Name=Mark+Llewellyn; Height=6%27+3%22; Color=blue
PATH	C:\Windows\system32;C:\Windows;C:\Windows\System32\Wbem;C:\Program Files\MySQL\MySQL Server 5.0\bin;C:\Program Files\QuickTime\QTSystem\
SystemRoot	C:\Windows

A blue callout box with a pointer arrow points to the "HTTP_COOKIE" row, which contains the value "Name=Mark+Llewellyn; Height=6%27+3%22; Color=blue". The text inside the callout box is: "Contents of the cookie stored on the client machine."

Cookies (cont.)

Actual text file holding cookie data for the cookie that was created in this example.

Dynamic Content in PHP

- Of all the strengths PHP exhibits as a server-side scripting language, perhaps its greatest strength lies in its ability to dynamically change XHTML output based on user input.
- In this final section of notes, we'll build on the examples we've constructed in the previous two sets of notes by combining `form.html` and `form.php` into one dynamic PHP document named `dynamicForm2.php`.
- We'll add error checking to the user input fields and inform the user of invalid entries on the form itself, rather than on an error page. If an error exists, the script maintains the previously submitted values in each form element.
- Finally, after the form has been successfully completed, we'll store the input from the user in a MySQL database.

Dynamic nature of the PHP form is illustrated when the user fails to enter proper information into the form. In this case, the user forgot to enter their first name. Error checking is in place on each user input location and the page is dynamically updated to reflect the error processing and correction capabilities. The database will not be updated until the user has correctly filled in all required fields.

Invoke PHP script to see contents of entire database if user clicks this link. Code begins on page 14.

The form created is self-submitting (i.e., it posts to itself). This is done by setting the action to dynamicForm2.php

```
<!-- create four text boxes for user input -->" );
foreach ( $inputlist as $inputname => $inputalt ) {
    $inputtext = $inputvalues[ $inputname ];

    print( "<img src = 'images/$inputname.gif'
        alt = '$inputalt' /><input type = 'text' name = '$inputname' value = "" . $$inputname . "" />" );
    if ( $formerrors[ ( $inputname )."error" ] == true )
        print( "<span style = 'color : red'>*</span>" );
    print( "<br />" );
}
print( "<span style = 'font-size : 10pt' >";
if ( $formerrors[ "phoneerror" ] ) print( "; color : red" );
print( ">Must be in the form (555)555-5555
</span><br /><br />
<img src = 'images/downloads.gif'
alt = 'Publications' /><br />
<span style = 'color: blue'>
Which magazine would you like information about?
</span><br />
<!-- create drop-down list containing magazine names -->
<select name = 'mag'>" );
foreach ( $maglist as $currmag ) {
    print( "<option" );
    if ( ( $currmag == $mag ) )
        print( " selected = 'true'" );
    print( ">$currmag</option>" );
}
```

The \$\$variable notation specifies variable variables. PHP permits the use of variable variables to allow developers to reference variables dynamically. The expression \$\$variable could also be written as \${\$variable} for added clarity.

```
print( "</select><br /><br />
<img src = 'images/os.gif' alt = 'Operating System' />
<br /><span style = 'color: blue'>
