Rule for figuring out what method gets

called
Obj.method(a, b)
 ↑ ref A ↑ Ref A ↑ Ref B
 ↑ ref C

Step 1 - look in the reference class of

this (object method was called on)

In example above, it's A.

We will look to see if a method exists in A that takes in an A and B (references).

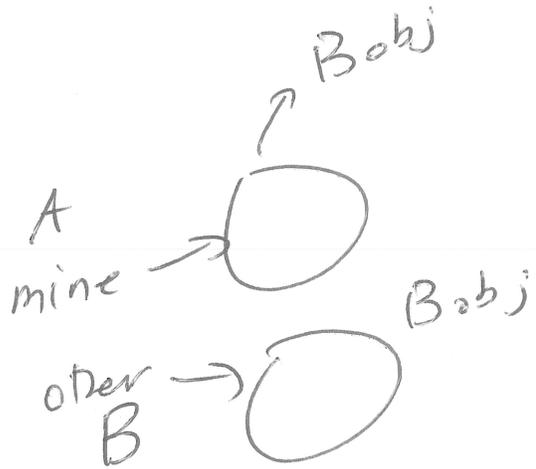

→ if this doesn't exist, we'll look at the class A inherits from, and, all the way down to Object. If no method is found code doesn't COMPILE.

Step 2 - once code compiles, find the method that matches by starting in the OBJECT class of this. find a matching method based on the ~~reference~~ reference types of the parameters.

A mine = new B()

B other = new B()

mine.f(other)

Why does CODE compile?

reference class of mine is A

goto class A and find a method that takes in a B

matching method WAS

f(A x) in class A

because a B IS-A A.

When finding a method at runtime,
since mine is OBJECT B, we look
in class B for a method with
signature f(A x) because that's what
allowed compilation.

f(B x) in B DOESN'T MATCH

So we look to CLASS A.

Modifications

1) Add a method to B:

$f(A\ x)$, prediction \rightarrow this will get CALLED in class B (match found!) ✓

2) Remove #1, Add to A ✓

$f(B\ x)$ prediction \rightarrow ONLY $f(B\ x)$ in class B will be called

3) Add both

same action as case 2.

Ex 2

A one → $\begin{matrix} & 14 \\ & 4 \\ x & \boxed{2} \end{matrix}$

A two → $\begin{matrix} & 4 \\ x & \boxed{2} \\ y & \boxed{4} \\ & 11 \end{matrix}$

C six → $\begin{matrix} x=2 & 4 & 1 \\ y=8 & & \\ z=6 & 15 \end{matrix}$

B four → $\begin{matrix} x & \boxed{2} \\ y & \boxed{8} \\ z & 3 \end{matrix}$

B three → $\begin{matrix} x & \boxed{2} \\ y & \boxed{7} \end{matrix}$

one. f(two) // binds + calls f(A) in A (1)

one. f(four) // my x = 4, your x = 2, your y = 8 (2)
binds + calls f(B) in A

two. f(three) // binds to f(B) in A calls f(B) in B (4)

four. f(five) // bound f(B) ^{in B} none in class C, called in class B (4)

Six. f(five) // six in class C for reference, five is class C for reference ~~but no~~ so match is f(C) in class C, compiler binds to 6 so this gets called.

after this
five prints as (2, 8, 9)
six prints as (4, 7, 15)

prints 3 (4, 29)
two. f(one) // binds to f(A) in class A
14 + 4 + 11 is 29 for compilation, CALLS ~~f(A)~~ f(A)
so two's (y = 29) in class B (3)

prints 5 (4, 10, 7)
four. f(two) // binds to f(A) in class B, for
adds 4 to z of compilation. CALLS f(A) in class C
four since OBJECT four is C.
