University of Central Florida

Introduction to JDBC

- JDBC was originally an acronym for Java Data Base Connectivity. Sun marketing now states this is no longer an acronym but the official name.
- JDBC is made up of about two dozen Java classes in the package `java.sql`. These classes provide access to relational data stored in a database or other table-oriented forms (like Excel, etc.).
- JDBC allows the programmer to use modern database features such as simultaneous connections to several databases, transaction management, precompiled statements with bind variables, calls to stored procedures, and access to metadata in the database dictionary.
- JDBC supports both static and dynamic SQL statements.
- The evolution of JDBC is shown on the next slide.

Evolution of JDBC

JDBC Version	Bundled with	Package Name	Contents
JDBC 1.0 (previously called 1.2)	JDK 1.1	java.sql	Basic Java client to database connectivity.
JDBC 2.0 core API	JDK 1.2 and later	java.sql	Added features such as scrollable result sets, batch updates, new data types for SQL-3, and programmable updates using the result set.
JDBC 2.0 optional API	J2EE and later	javax.sql	Can be downloaded from www.java.sun.com/products/jdbc/ . Contains database server-side functionality. Prepares the ground for the use of database-aware Java beans.
JDBC 2.1 optional API	Not bundled	javax.sql	Incremental improvement and additions over the 2.0 API.
JDBC 3.0 core API	JDK 1.4 and later	java.sql	Adds support for connection pooling, statement pooling, and a migration path to the Connector Architecture.

Connecting To A Database

- A database works in the classic client/server fashion. There is one database and many clients talk to it. (Larger applications may have multiple databases, but they can be considered independently for our purposes.)
- As we've seen in the earlier sections of notes dealing with networking, the clients are typically remote systems communicating over TCP/IP networks.
- In a 2-tier system, the clients talk directly to the database while in a 3-tier system, the clients talk to a business logic server which in turn talks to the database. The business logic server would also contain server-side JDBC functionality.

Connecting To A Database (cont.)

- A JDBC driver is typically available from the database vendor of the database to which you wish to connect.
- There are several different kinds of drivers depending on whether it was written in Java or native code, or whether it talks directly to the database or through another database access protocol (such as Microsoft's ODBC). From an application programmer's point of view, none of this matters very much as long as you have a working JDBC driver, you really don't care how it works (although your client may if its too slow!).
- JDBC supports four categories of drivers which are detailed in the table on the next page.

JDBC Driver Types

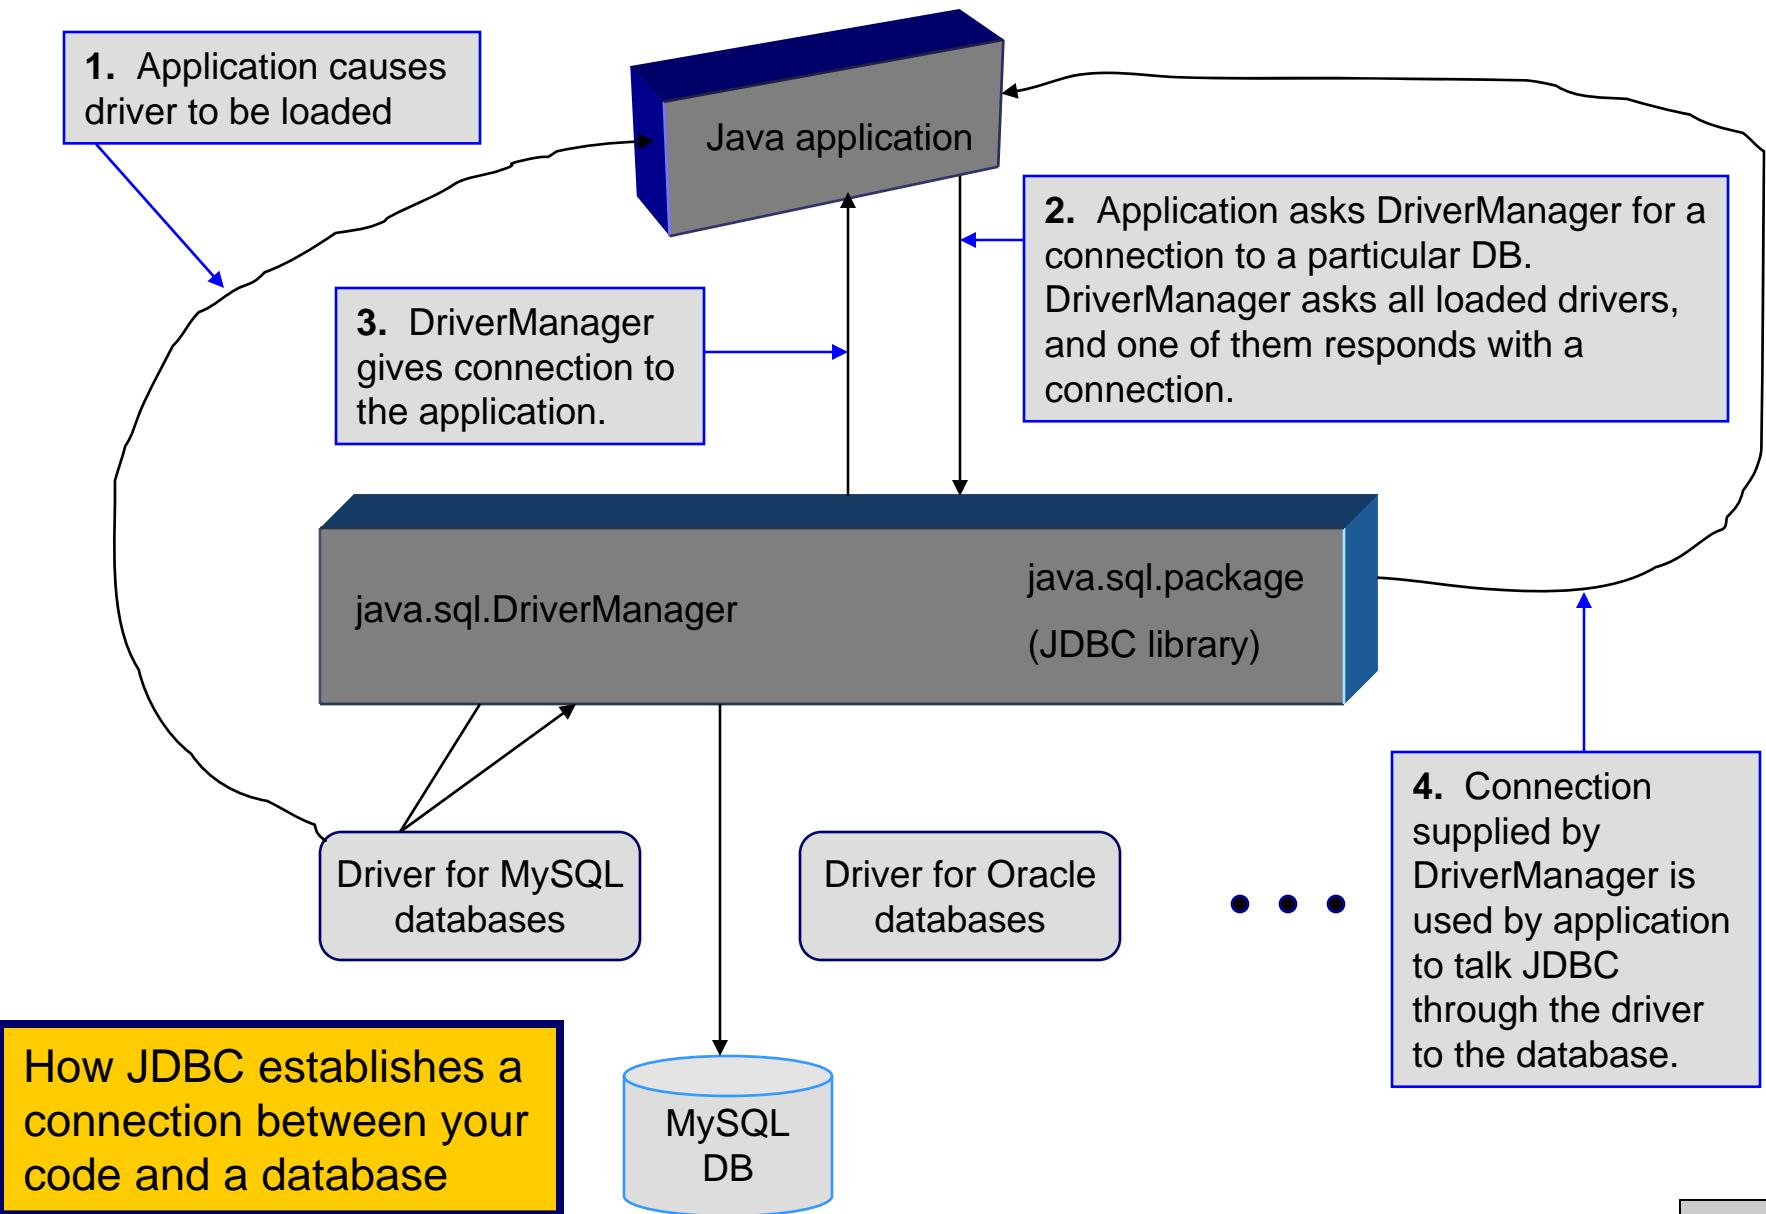

Type	Description
1	JDBC-to-ODBC Bridge Driver – connects Java to a Microsoft ODBC (Open Database Connectivity) data source. This driver requires the ODBC driver to be installed on the client computer and configuration of the ODBC data source. This driver is used to allow Java programmers to build data-driver Java applications before the database vendor supplies a Type 3 or Type 4 driver. In general, this will not be used too much these days.
2	Native-API, Part Java Drivers – enable JDBC programs to use database-specific APIs (normally written in C or C++) that allow client programs to access databases via the Java Native Interface. This driver translates JDBC into database-specific code. Reasons for use are similar to Type 1.
3	JDBC-Net Pure Java Drivers – take JDBC requests and translate them into a network protocol that is not database specific. These requests are sent to a server, which translates the database requests into a database-specific protocol.
4	Native-protocol Pure Java Drivers – convert JDBC requests to database-specific network protocols, so that Java programs can connect directly to a database.

Some Popular JDBC Drivers

RDBMS	JDBC Driver Name
MySQL	Driver Name com.mysql.jdbc.Driver Database URL format: jdbc:mysql://hostname/databaseName
Oracle	Driver Name: oracle.jdbc.driver.OracleDriver Database URL format: jdbc:oracle:thin@hostname:portnumber:databaseName
DB2	Driver Name: COM.ibm.db2.jdbc.net.DB2Driver Database URL format: jdbc:db2:hostname:portnumber/databaseName
Access	Driver Name: com.jdbc.odbc.JdbcOdbcDriver Database URL format: jdbc:odbc:databaseName

Loading A JDBC Driver

- The first step (as illustrated in the previous slide) is to load a JDBC driver.
- If your application connects to several different types of databases, all of their respective drivers must be loaded.
- The Java statement to load a JDBC driver is:

```
Class.forName( " JDBC Driver Class " );
```

- You don't need to create an instance of the driver class. Simply getting the class loaded is enough. Each JDBC driver has a static initializer that is run when the class is loaded, and in that code the driver registers itself with the JDBC. The JDBC driver does about 90% of the work that is done in JDBC.

Establishing a Connection

- The second step involves the Java application requesting a connection to a database, using a string that looks like a URL as an argument.
- The JDBC library contains the class `java.sql.Connection` that knows how to use this string to guide it in its search for the correct database. As was shown in the table on page 7, the exact format of the pseudo-URL string will vary with each database, but it typically starts with “`jdbc:`” to indicate the protocol that will be used (just as “`http:`” indicates to a web server that you are using the hypertext transport protocol).
- The Java statement to connect to a database invokes the static method `getConnection(databaseURL)` in the `DriverManager` class:

```
Connection connection =  
    DriverManager.getConnection(url, username, password);
```

Optional parameters

Establishing a Connection (cont.)

- Behind the scenes, the `DriverManager` calls every JDBC driver that has been registered, and asks it if the URL is one that it can use to guide it to its database.
- If the URL is properly presented, it will be recognized by at least one of the drivers.
- The first driver to connect to its database with this URL, username, and password, will be used as the channel of communication.
- The application program gets back a `Connection` object (strictly speaking it gets an object that implements the `Connection` interface).
- The session has now been established and the connection is now used for communication between the application program and the database.
- You can think of the `Connection` object as cable linking your application program to the database.

Establishing a Connection (cont.)

- Connecting to a database is a time consuming operation. As a result, most databases have a way to share connections among several different processes. This arrangement is known as connection pooling.
- In summary:
 - Your application program knows which database it wants to talk to, and hence which database driver it needs to load.
 - The JDBC driver manager knows how to establish the JDBC end of a database connection.
 - The driver knows how to establish the database end of things.
 - The driver manager gives the application a connection into which you can pour standard SQL queries and get results.

Creating Statements

- If the Connection object can be viewed as a cable between your application program and the database, an object of Statement can be viewed as a cart that delivers SQL statements for execution by the database and brings the result back to the application program.
- Once a Connection object is created, you can create statements for executing SQL statements as follows:

```
Statement statement = connection.createStatement();
```

- At this point, you're now ready to begin issuing SQL commands to the database and getting back results. The table on the following page illustrates some of the methods contained in `java.sql.Connection`.

Selected Methods In `java.sql.Connection`

Method	Purpose
<code>Statement createStatement()</code>	Returns a statement object that is used to send SQL to the database.
<code>PreparedStatement preparedStatement(String sql)</code>	Returns an object that can be used for sending parameterized SQL statements.
<code>CallableStatement prepareCall(String sql)</code>	Returns an object that can be used for calling stored procedures.
<code>DatabaseMetaData getMetaData()</code>	Gets an object that supplied database configuration information.
<code>boolean isClosed()</code>	Reports whether the database is currently open or not.
<code>void commit()</code>	Makes all changes permanent since previous commit.rollback.
<code>void rollback()</code>	Undoes and discards all changes done since the previous commit/rollback.

Selected Methods In `java.sql.Connection`

(cont.)

Method	Purpose
<code>void setAutoCommit (boolean yn)</code>	Restores/removes auto-commit mode, which does an automatic commit after each statement. The default case is AutoCommit is on.
<code>void close()</code>	Closes the connection and releases the JDBC resources for the connection.
<code>boolean isReadOnly()</code>	Retrieves whether this Connection object is in read-only mode.
<code>void setReadOnly(boolean yn)</code>	Puts this connection in read-only mode as a hint to the driver to enable database optimizations.

Creating Statements (cont.)

- The methods illustrated in the previous table are invoked on the Connection object returned by the JDBC driver manager.
- The connection is used to create a Statement object.
- The Statement object contains the methods that allow you to send the SQL statements to the database.
- Statement objects are very simple objects which allow you to send SQL statements as Strings.
- Here is how you would send a select query to the database:

```
Statement myStmt = connection.createStatement();  
ResultSet myResult; ← More on  
ResultSet later  
  
myResult = myStmt.executeQuery( "SELECT * FROM bikes;" );
```

Creating Statements (cont.)

- The different SQL statements have different return values. Some of them have no return value, some of them return the number of rows affected by the statement, and others return all the data extracted by the query.
- To handle these varied return results, you'll need to invoke a different method depending on what type of SQL statement you are executing.
- The most interesting of these is the SELECT statement that returns an entire result set of data.
- The following table highlights some of the methods in `java.sql.Statement` to execute SQL statements.

Some Methods in java.sql.Statement to Execute SQL Statements

SQL statement	JDBC statement to use	Return Type	Comment
SELECT	executeQuery(String sql)	ResultSet	The return value will hold the data extracted from the database.
INSERT, UPDATE, DELETE, CREATE, DROP	executeUpdate(String sql)	int	The return value will give the count of the number of rows changed , or zero otherwise.
Stored procedure with multiple results	execute(String sql)	boolean	The return value is true if the first result is a ResultSet, false otherwise.

Putting It All Together – A Simple Example

- Let's put all these pieces together and develop a Java application that will connect to our bikedb database, execute a query, and return the results.
- This application will show, in the simplest terms, how to load the JDBC driver, establish a connection, create a statement, have the statement executed, and return the results to the application.
- The code is shown on the next page with results on the following page.

```

// Very basic JDBC example showing loading of JDBC driver, establishing
// a connection, creating a statement, executing a simple SQL query, and
// displaying the results.
import java.sql.*;
public class SimpleJdbc {
    public static void main(String[] args)
        throws SQLException, ClassNotFoundException {
        // Load the JDBC driver
        Class.forName("com.mysql.jdbc.Driver");
        System.out.println("Driver loaded");
        // Establish a connection
        Connection connection = DriverManager.getConnection
            ("jdbc:mysql://localhost/bikedb", "root", "root");
        System.out.println("Database connected");
        // Create a statement
        Statement statement = connection.createStatement();
        // Execute a statement
        ResultSet resultSet = statement.executeQuery
            ("select bikename,cost,mileage from bikes");
        // Iterate through the result set and print the returned results
        while (resultSet.next())
            System.out.println(resultSet.getString(1) + "\t" +
                resultSet.getString(2) + "\t" + resultSet.getString(3));
        // Close the connection
        connection.close();
    }
}

```

The diagram illustrates the execution flow of the JDBC code. It consists of several orange rectangular boxes with black outlines, each containing a label. Blue arrows point from specific lines of code in the Java script to their corresponding boxes. The labels are:

- Load JDBC driver**: Points to the line `Class.forName("com.mysql.jdbc.Driver");`
- Establish connection specifying database, username, and password.**: Points to the line `DriverManager.getConnection("jdbc:mysql://localhost/bikedb", "root", "root");`
- Create statement**: Points to the line `Statement statement = connection.createStatement();`
- Execute query**: Points to the line `ResultSet resultSet = statement.executeQuery("select bikename,cost,mileage from bikes");`
- Iterate through resultSet**: Points to the line `while (resultSet.next())`
- Close connection**: Points to the line `connection.close();`

```

Result Sets

- A ResultSet object is similar to a 2D array. Each call to `next()` moves to the next record in the result set. You must call `next()` before you can see the first result record, and it returns false when there are no more result records (this makes it quite convenient for controlling a while loop). (Also remember that the Iterator `next()` returns the next object and not a true/false value.)
- The class ResultSet has “getter” methods `getBlob()`, `getBigDecimal()`, `getDate()`, `getBytes()`, `getInt()`, `getLong()`, `getString()`, `getObject()`, and so on, for all the Java types that represent SQL types for a column name and column number argument. Look at the documentation for `java.sql.ResultSet` for a complete listing of the methods.

Result Sets (cont.)

- A default ResultSet object is not updatable and has a cursor that only moves forward.
- Many database drivers support scrollable and updatable ResultSet objects.
 - Scrollable result sets simply provide a cursor to move backwards and forwards through the records of the result set.
 - Updatable result sets provide the user with the ability to modify the contents of the result set and update the database by returning the updated result set. NOTE: Not all updates can be reflected back into the database. It depends on the complexity of the query and how the data in the result set was derived. In general, base relation attribute values can be modified through an updatable result set. We'll see an example of this later.

ResultSet Constants for Specifying Properties

ResultSet static type constant	Description
TYPE_FORWARD_ONLY	Specifies that the ResultSet cursor can move only in the forward direction, from the first row to the last row in the result set.
TYPE_SCROLL_INSENSITIVE	Specifies that the ResultSet cursor can scroll in either direction and that the changes made to the result set during ResultSet processing are not reflected in the ResultSet unless the database is queried again.
TYPE_SCROLL_SENSITIVE	Specifies that the ResultSet cursor can scroll in either direction and that changes made to the result set during ResultSet processing are reflected immediately in the ResultSet.
ResultSet static concurrency constant	Description
CONCUR_READ_ONLY	Specifies that the ResultSet cannot be updated (i.e. changes to it will not be reflected into the database).
CONCUR_UPDATABLE	Specifies that the ResultSet can be updated (i.e. changes to it will be reflected into the database using ResultSet update methods).

ResultSet Examples

- The following two examples clarify the various constants which can be applied to result sets (assume that connection is a valid Connection).

```
//creates a ResultSet which is scrollable, insensitive  
//to changes by others and updatable.
```

```
Statement stmt = connection.createStatement(  
    (ResultSet.TYPE_SCROLL_INSENSITIVE,  
     ResultSet.CONCUR_UPDATABLE) ;
```

```
//creates a ResultSet which is scrollable, sensitive  
//to changes by others and updatable.
```

```
Statement stmt = connection.createStatement(  
    (ResultSet.TYPE_SCROLL_SENSITIVE,  
     ResultSet.CONCUR_UPDATABLE) ;
```

Another Example

- In the previous example, notice that in the output, there was no information about what the columns represent. The output appears to be just data rather than information.
- A more sophisticated example, will access the database and use the metadata to provide more significance to the results.
- In the next example, we do just that by retrieving metadata from the database to help with the display of the result set.

DisplayBikes JDBC Application – page 1

```
// Displaying the contents of the bikes table.  
import java.sql.Connection;  
import java.sql.Statement;  
import java.sql.DriverManager;  
import java.sql.ResultSet;  
import java.sql.ResultSetMetaData;  
import java.sql.SQLException;  
  
public class DisplayBikes{  
    // JDBC driver name and database URL  
    static final String JDBC_DRIVER = "com.mysql.jdbc.Driver";  
    static final String DATABASE_URL = "jdbc:mysql://localhost/bikedb2";  
  
    // launch the application  
    public static void main( String args[] ) {  
        Connection connection = null; // manages connection  
        Statement statement = null; // query statement  
  
        // connect to database bikes and query database  
        try  
        {  
            Class.forName( JDBC_DRIVER ); // load database driver class  
            Connection conn = DriverManager.getConnection( DATABASE_URL, "root", "password" );  
            Statement stmt = conn.createStatement();  
            ResultSet rs = stmt.executeQuery( "SELECT * FROM bikes" );  
            while( rs.next() )  
            {  
                System.out.println( rs.getString( "id" ) + " " + rs.getString( "name" ) );  
            }  
        }  
        catch( SQLException se )  
        {  
            se.printStackTrace();  
        }  
    }  
}
```

Type 4 JDBC driver (pure Java driver) to connect to MySQL RDBMs

Specify name of database to connect to as well as JDBC driver protocol.

See Note on Page 31

DisplayBikes JDBC Application – page 2

```
// establish connection to database  
connection =  
    DriverManager.getConnection( DATABASE_URL, "root", "root" );  
  
// create Statement for querying database  
statement = connection.createStatement();  
  
// query database  
ResultSet resultSet = statement.executeQuery(  
    "SELECT bikename, cost, mileage FROM bikes" );  
  
// process query results  
ResultSetMetaData metaData = resultSet.getMetaData();  
int numberOfColumns = metaData.getColumnCount();  
System.out.println( "Bikes Table of bikedb Database:" );  
  
for ( int i = 1; i <= numberOfColumns; i++ )  
    System.out.printf( "%-20s\t", metaData.getColumnName( i ) );  
System.out.println();  
  
while ( resultSet.next() )  
{  
    for ( int i = 1; i <= numberOfColumns; i++ )  
        System.out.printf( "%-20s\t", resultSet.getObject( i ) );  
}
```

The MySQL query to be executed remotely.

Get metadata from the resultSet to be used for the output formatting.

DisplayBikes JDBC Application – page 3

```
        System.out.println();
    } // end while
} // end try
catch ( SQLException sqlException ) {
    sqlException.printStackTrace();
    System.exit( 1 );
} // end catch
catch ( ClassNotFoundException classNotFound ) {
    classNotFound.printStackTrace();
    System.exit( 1 );
} // end catch
finally { // ensure statement and connection are closed properly
    try {
        statement.close();
        connection.close();
    } // end try
    catch ( Exception exception ) {
        exception.printStackTrace();
        System.exit( 1 );
    } // end catch
} // end finally
} // end main
} // end class DisplayBikes
```

Note Regarding Static Method `forName`

- The database driver must be loaded before connecting to the database. The static method `forName` of class `Class` is used to load the class for the database driver.
- This method throws a checked exception of type `java.lang.ClassNotFoundException` if the class loader cannot locate the driver class.
- To avoid this exception, you need to include the `mysql-connector-java-5.0.3-bin.jar` in your program's classpath when you execute the program.
- Copy the `mysql-connector-java-5.0.3-bin.jar` file to the JRE's `lib\ext` directory. (available on the class web-site, if you didn't already get it from MySQL (www.mysql.com)).

Querying the bikedb MySQL Database

- In this example, we'll allow the user to enter any valid MySQL query into the Java application to query the bikes table of the bikedb database.
- The results of the query are returned in a JTable, using a TableModel object to provide the ResultSet data to the JTable.
- Class ResultSetTableModel performs the connection to the database and maintains the ResultSet.
- Class DisplayQueryResults creates the GUI and specifies an instance of class ResultSetTableModel to provide the data for the JTable.

Class: ResultSetTableModel – page 1

```
// A TableModel that supplies ResultSet data to a JTable.  
import java.sql.Connection;  
import java.sql.Statement;  
import java.sql.DriverManager;  
import java.sql.ResultSet;  
import java.sql.ResultSetMetaData;  
import java.sql.SQLException;  
import javax.swing.table.AbstractTableModel;  
  
// ResultSet rows and columns are counted from 1 and JTable  
// rows and columns are counted from 0. When processing  
// ResultSet rows or columns for use in a JTable, it is  
// necessary to add 1 to the row or column number to manipulate  
// the appropriate ResultSet column (i.e., JTable column 0 is  
// ResultSet column 1 and JTable row 0 is ResultSet row 1).  
public class ResultSetTableModel extends AbstractTableModel {  
    private Connection connection;  
    private Statement statement;  
    private ResultSet resultSet;  
    private ResultSetMetaData metaData;  
    private int numberOfRows;  
  
    // keep track of database connection status  
    private boolean connectedToDatabase = false;
```

Class: ResultSetTableModel – page 2

```
// constructor initializes resultSet and obtains its meta data object;  
// determines number of rows  
public ResultSetTableModel( String driver, String url,  
    String username, String password, String query )  
throws SQLException, ClassNotFoundException  
{  
    // load database driver class  
    Class.forName( driver );  
  
    // connect to database  
    connection = DriverManager.getConnection( url, username, password );  
  
    // create Statement to query database  
    statement = connection.createStatement(  
        ResultSet.TYPE_SCROLL_INSENSITIVE,  
        ResultSet.CONCUR_READ_ONLY );  
  
    // update database connection status  
    connectedToDatabase = true;  
  
    // set query and execute it  
    setQuery( query );  
} // end constructor ResultSetTableModel
```

Class: ResultSetTableModel – page 3

```
// get class that represents column type
public Class getColumnClass( int column ) throws IllegalStateException {
    // ensure database connection is available
    if ( !connectedToDatabase )
        throw new IllegalStateException( "Not Connected to Database" );

    // determine Java class of column
    try {
        String className = metaData.getColumnClassName( column + 1 );
        // return Class object that represents className
        return Class.forName( className );
    } // end try
    catch ( Exception exception ) {
        exception.printStackTrace();
    } // end catch

    return Object.class; // if problems occur above, assume type Object
} // end method getColumnClass

// get number of columns in ResultSet
public int getColumnCount() throws IllegalStateException {
    // ensure database connection is available
    if ( !connectedToDatabase )
        throw new IllegalStateException( "Not Connected to Database" );
```

Class: ResultSetTableModel – page 4

```
// determine number of columns
try {
    return metaData.getColumnCount();
} // end try
catch ( SQLException sqlException ) {
    sqlException.printStackTrace();
} // end catch

return 0; // if problems occur above, return 0 for number of columns

Execution of DisplayQueryResults

The screenshot shows a window titled "Displaying Query Results". In the top-left corner, there is a small icon of a flame. The main area contains a query input field with the text "SELECT * FROM bikes" and a "Submit Query" button. Below the input field is a table with the following data:

bikename	size	color	cost	purchased	mileage
Colnago Dream Rabobank	60	blue/orange	5500	Jul 27, 2002	4300
Bianchi Evolution 3	58	celeste	4800	Nov 16, 2003	2000
Eddy Merckx Molteni	58	orange	5100	Aug 12, 2004	0
Eddy Merckx Domo	58	blue/black	5300	Feb 2, 2004	0
Battaglin Carrera	60	red/white	4000	Mar 14, 2001	11200
Gianni Motta Personal	59	red/green	4400	May 1, 2000	8700
Gios Torino Super	60	blue	2000	Nov 8, 1998	9000
Schwinn Paramount P14	60	blue	1800	Mar 1, 1992	200
Bianchi Corse Evo 4	58	celeste	5700	Dec 22, 2004	300
Colnago Superissimo	59	red	3800	Mar 1, 1996	13000

Display of default query results from DisplayQueryResults application

Execution of DisplayQueryResults

The screenshot shows a window titled "Displaying Query Results". At the top left is a small icon of a computer monitor with a flame. The main area contains a SQL query:

```
SELECT *  
FROM bikes  
WHERE color = 'blue';
```

To the right of the query is a "Submit Query" button. Below the query is a table displaying the results:

bikename	size	color	cost	purchased	mileage
Gios Torino Super	60	blue	2000	Nov 8, 1998	9000
Schwinn Paramount P14	60	blue	1800	Mar 1, 1992	200

Display of user-formed query results from DisplayQueryResults application

The PreparedStatement Interface

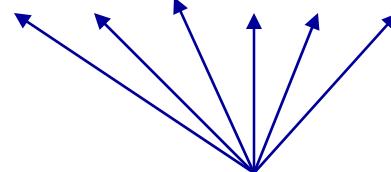

- In the previous examples, once we established a connection to a particular database, it was used to send an SQL statement from the application to the database.
- The Statement interface is used to execute static SQL statements that contain no parameters.
- The PreparedStatement interface, which extends the Statement interface, is used to execute a precompiled SQL statement with or without IN parameters.
- Since the SQL statements are precompiled, they are extremely efficient for repeated execution.

The PreparedStatement Interface (cont.)

- A PreparedStatement object is created using the preparedStatement method in the Connection interface.

```
Statement pstmt = connection.prepareStatement  
( "insert into bikes (bikename, size, color,  
cost, purchased, mileage) +  
values ( ?, ?, ?, ?, ?, ? )" );
```

Placeholders for the values that will be dynamically provided by the user.

The PreparedStatement Interface (cont.)

- As a subinterface of Statement, the PreparedStatement interface inherits all the methods defined in Statement. It also provides the methods for setting parameters in the object of PreparedStatement.
- These methods are used to set the values for the parameters before executing statements or procedures.
- In general, the set methods have the following signature:

```
setX (int parameterIndex, X value);
```

where X is the type of parameter and parameterIndex is the index of the parameter in the statement.

The PreparedStatement Interface (cont.)

- As an example, the method

```
setString( int parameterIndex, String value)
```

sets a String value to the specified parameter.

- Once the parameters are set, the prepared statement is executed like any other SQL statement where `executeQuery()` is used for SELECT statements and `executeUpdate()` is used for DDL or update commands.
- These two methods are similar to those found in the Statement interface except that they have no parameters since the SQL statements are already specified in the `prepareStatement` method when the object of a PreparedStatement is created.

FindBikeUsingPreparedStatement

```
import javax.swing.*;
import java.sql.*;
import java.awt.*;
import java.awt.event.*;

public class FindBikeUsingPreparedStatement extends JApplet {
    boolean isStandalone = false;
    private JTextField jtfbike = new JTextField(25);
    private JTextField jfcost = new JTextField(6);
    private JButton jbtShowCost = new JButton("Show Bike Cost Info");

    // PreparedStatement for executing queries
    private PreparedStatement pstmt;
```

PreparedStatement object

```

JPanel jPanel1 = new JPanel();
jPanel1.add(new JLabel("Bike Name"));
jPanel1.add(jtfbike);
jPanel1.add(jbtShowCost);
this.getContentPane().add(jPanel1, BorderLayout.NORTH);
}

private void initializeDB() {
try {
// Load the JDBC driver
Class.forName("com.mysql.jdbc.Driver");
System.out.println("Driver loaded");
// Establish a connection
Connection connection = DriverManager.getConnection
("jdbc:mysql://localhost/bikedb", "root", "root");
System.out.println("Database connected");

String queryString = "select cost from bikes where bikename = ?";
// Create a statement
stmt = connection.prepareStatement(queryString);
}
catch (Exception ex) {
ex.printStackTrace();
}
}

```

queryString contains the SQL statement with the ? Placeholder for the value to be determined at run-time.

Invoke the preparedStatement() method on the connection.

```

private void jbtShowCostActionPerformed(ActionEvent e) {
    String bikename = jtfbike.getText();
    String cost = jtfcost.getText();
    try {
        pstmt.setString(1, bikename);
        ResultSet rset = pstmt.executeQuery();
        if (rset.next()) {
            String price = rset.getString(1);
            // Display result in a dialog box
            JOptionPane.showMessageDialog(null, bikename + " cost $" + price);
        }
        else { // Display result in a dialog box
            JOptionPane.showMessageDialog(null, "Bike Not Found");
        }
    }
    catch (SQLException ex) {
        ex.printStackTrace();
    }
}

```

Set first parameter value for PreparedStatement object

Execute query using PreparedStatement object

Get data from results set returned by JDBC.

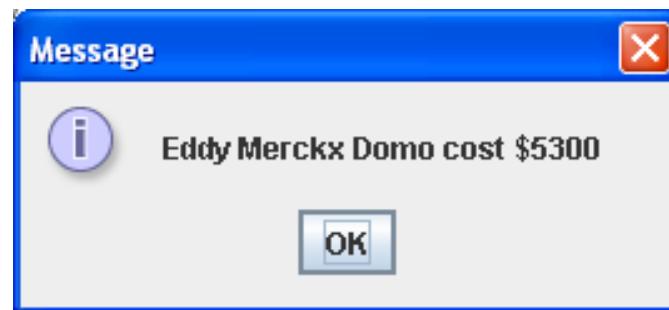

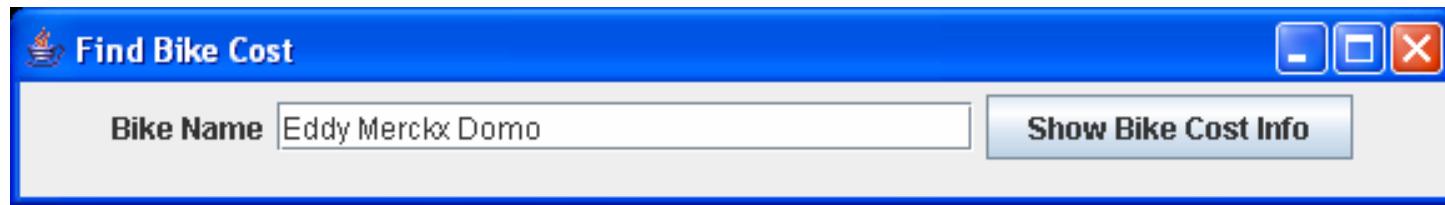

```

/** Main method */
public static void main(String[] args) {
    FindBikeUsingPreparedStatement applet = new
    FindBikeUsingPreparedStatement();
    JFrame frame = new JFrame();
    frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    frame.setTitle("Find Bike Cost");
    frame.getContentPane().add(applet, BorderLayout.CENTER);
    applet.init(); applet.start(); frame.setSize(580, 80);
    Dimension d = Toolkit.getDefaultToolkit().getScreenSize();
    frame.setLocation((d.width - frame.getSize().width) / 2,
        (d.height - frame.getSize().height) / 2);
    frame.setVisible(true);
}

```

Output from FindBikeUsingPreparedStatement

The RowSet Interface (cont.)

- Interface RowSet provides several set methods that allow the programmer to specify the properties needed to establish a connection (such as the database URL, user name, password, etc.) and a create a Statement (such as a query).
- Interface RowSet also provides several get methods that return these properties.
- More information on these methods can be found at:
<http://java.sun.com/j2se/1.5.0/docs/api/javax/sql/RowSet.html>

The RowSet Interface (cont.)

- RowSet is part of the `javax.sql` package.
- Although part of the Java 2 Standard Edition, the classes and interfaces of package `javax.sql` are most often used in the context of the Java 2 Platform Enterprise Edition (J2EE).
- We will get to some J2EE development later in the semester. You can learn more about J2EE at www.java.sun.com/j2ee.

Using the RowSet Interface

- There are two types of RowSet objects – **connected** and **disconnected**.
- A **connected RowSet** object connects to the database once and remains connected until the application terminates.
- A **disconnected RowSet** object connects to the database, executes a query to retrieve the data from the database and then closed the connection. A program may change the data in a disconnected RowSet while it is disconnected. Modified data can be updated to the database after a disconnected RowSet reestablishes the connection with the database.

Using the RowSet Interface (cont.)

- J2SE 5.0 package javax.sql.rowset contains two subinterfaces of RowSet – JdbcRowSet and CachedRowSet.
- **JdbcRowSet**, a connected RowSet, acts as a wrapper around a ResultSet object, and allows programmers to scroll through and update the rows in the ResultSet object. Recall that by default, a ResultSet object is non-scrollable and read only – you must explicitly set the result-set type constant to TYPE_SCROLL_INSENSITIVE and set the result set concurrency constant to CONCUR_UPDATEABLE to make a ResultSet object scrollable and updatable.

Using the RowSet Interface (cont.)

- A JdbcRowSet object is scrollable and updatable by default.
- CachedRowSet, a disconnected RowSet, caches the data of a ResultSet in memory and disconnects from the database. Like JdbcRowSet, a CachedRowSet object is scrollable and updatable by default.
- A CachedRowSet is also serializable, so it can be passed between Java applications through a network.
- However, a CachedRowSet has a limitation – the amount of data that can be stored in memory is limited.
- There are three other subinterfaces in this package (FilteredRowSet, WebRowSet, and JoinRowSet).

Using the RowSet Interface (cont.)

- The code example on the next couple of pages illustrates the use of the RowSet interface.
- Notice that unlike the TableSet version in the previous set of notes, the connection is made and the query executed automatically.

Class: JdbcRowSetTest – page 1

```
// Displaying the contents of the bikes table using JdbcRowSet.  
import java.sql.ResultSetMetaData;  
import java.sql.SQLException;  
import javax.sql.rowset.JdbcRowSet;
